

Quota vs Quality?

Long-Term Gains from an Unusual Gender Quota

Abstract

We investigate the potential equity-efficiency trade-offs from representation quotas. In particular, we study the effect of abolishing a 40% quota for male primary school teachers on pupils' long run outcomes in Finland. The quota had advantaged academically lower scoring male applicants in university admissions, and its removal cut the share of men among new teachers by half. We show that combining this reform with the timing of union-mandated teacher retirements creates quasi-random variation in the local share of male teachers. We then document how quota-induced changes in local teacher gender composition affect pupils' outcomes in the long-run. Using comprehensive register data, we find that pupils exposed to a higher share of male quota teachers during primary school have higher educational attainment and labor force attachment at age 25. Pupils of both genders benefit similarly from exposure to male quota teachers. Our findings are consistent with male quota teachers contributing valuable qualities to school environments that are not sufficiently captured by the teacher selection process in absence of the quota.

We are grateful to David Yanagizawa-Drott, Joachim Voth, Claudia Goldin and Ulf Zöllitz for their guidance throughout this project. We thank Sara Bagagli, Anne Sofie Beck Knudsen, Augustin Bergeron, Anne Brenøe, Lorenzo Casaburi, Ana Costa-Ramón, Alessandro Ferrari, Matteo Greco, David Hémous, Andrea Hofer, Kristiina Huttunen, Daniel Kopp, Mika Kortelainen, Ross Mattheis, Morten Olsen, Claude Raisaro, Heather Sarsons, and Hanna Virtanen for helpful comments and suggestions. We thank Topias Jalo and his colleagues at Statistics Finland, as well as the administrative staff at the Universities of Tampere and Zurich for their support. We gratefully acknowledge financial support from the Yrjö Jahnsson foundation.

1 Introduction

Are affirmative action policies, such as quotas, costly for economic efficiency? On one hand, when quotas in educational institutions and workplaces are binding, they require these organizations to “lower the bar” by admitting applicants who would have been rejected otherwise. As quotas force a decision maker to deviate from her preferred ranking of candidates, the overall quality of successful applicants may be lower (Welch, 1976; Lundberg and Startz, 1983; Arcidiacono and Lovenheim, 2016). Cast in this light, affirmative action policies may achieve a distributional goal only at a cost of lower productivity.

In contrast to this reasoning, affirmative action policies may raise economic efficiency when evening out differences that arise from unequal opportunities that are unrelated to inherent potential ability: In this case, affirmative action measures may improve the allocation of talent in the economy (Hsieh et al., 2019; Coate and Loury, 1993; Becker, 1957).

Even in the absence of explicit discriminatory barriers, differential treatment of underrepresented groups may be desirable when selection processes operate under imperfect knowledge of candidates’ potential abilities (Holzer and Neumark, 2000). This is the case in settings in which multiple dimensions of skill determine output, but selection criteria are limited to specific subsets of cognitive scores (Heckman et al., 2006; Deming, 2017; Bell et al., 2019; Siniscalchi and Veronesi, 2021). A similar reasoning applies to environments in which there are complementarities between groups that materialize in production, such that diversity itself augments productivity. Taken together, these countervailing forces indicate that whether a representation quota is costly or output-enhancing is ultimately an empirical question whose answer depends on the specifics of the setting.

In this paper, we document that a quota - beyond merely achieving a representational goal - raised efficiency in the relevant industry by correcting a mis-allocation of talent. Leveraging a unique policy experiment in Finland, we trace out how a quota-induced shift in the gender composition of an entire occupation affects output in the long run. We study how the termination of a quota for male primary school teachers in Finland influenced pupils’ educational pathways and subsequent labor force attainment. Specifically, this quota had reserved 40% of slots in admissions for primary school teacher studies at Finnish universities for male applicants, advantaging academically lower-scoring male candidates. The removal of the quota resulted in a sharp drop in the share of men among admits to primary school teacher studies from about 40% to 20% (Uusiautti and Määttä, 2013; Räihä, 2010).

Our identification strategy isolates exogenous variation in pupils’ exposure to male quota teachers with a differences-in-differences instrumental variables (DiD-IV) framework: To instrument for the local teacher gender composition that pupils experience in primary school, we use the lifting of the quota together with the timing of local demand shocks for new teachers. These demand shocks arise from local teachers reaching the union-mandated teacher retirement age when they turn 60. The first stage uses the differential timing of retirements across municipalities: Intuitively, municipalities in which teachers turn 60 while the quota is still in place will hire

new teachers from a rookie teacher market with quota men, compared to municipalities whose teachers turn 60 just after the quota was abolished.¹ The exclusion restriction in this set-up requires that teacher retirements do not differentially affect pupil outcomes in the post-quota period except via teacher gender composition. Our empirical strategy addresses this by comparing pupils who experience similar exposure to new teachers via retirements, but face a different gender composition of those rookie teachers due to the lifting of the quota.

We start by outlining a simple conceptual framework of university admissions that derives conditions under which a representation quota results in lower or higher total ability of admitted candidates. When the selection criterion fully reflects candidate ability, introducing a binding quota comes at the cost of admitting less qualified candidates. In contrast, there may be efficiency gains from a quota when the selection criterion is negatively correlated with minority group status and insufficiently captures the potential ability of candidates: This can be the case both when the mapping between the selection criterion and ability differs across groups, and when there are complementarities in production between groups. Embedding same-identity role model effects within this framework, we derive testable predictions for our specific setting.

We then turn to examine the efficiency effects of the quota in the Finnish context empirically. First, we document how the lifting of the quota affected the local gender composition of teachers at the municipal level: Once the primary teacher cohorts that studied without the quota enter the market for rookie teachers in 1994, each retiring teacher is 20 percentage points less likely to be replaced with a male teacher relative to the quota period. These changes in the local teacher gender composition are accompanied by small, but noisily measured, increases in local teachers' average academic scores – consistent with the notion that lower scoring men are no longer admitted to primary teacher studies once the quota is abolished.

We proceed to study how these changes affect pupils, using comprehensive register data from 1988 to 2018 to trace out pupils' education and labor market pathways until age 25. Using the timing of teacher age-based retirements as an instrument for the local teacher gender composition, we show that pupils exposed to a higher share of male teachers via the quota have higher educational and labor force attainment in the long run: At age 25, these children are .09 standard deviations (SD) more likely to be a student or actively participating in the labor market for a 1 SD increase in the share of male quota teachers.² In terms of educational attainment, we observe a shift to higher qualifications throughout the educational attainment distribution: For practically-oriented vocational degrees, pupils are more likely to have additional advanced qualifications instead of a basic three-year degree. For academic tracks, pupils are more likely to have obtained a university level BA degree by age 25.

To better understand from where these differences in long-term outcomes originate, we use rich register data to closely track pupils' educational trajectory after finishing compulsory school-

¹We label as “quota men” those male teachers who were only able to enter primary teachers studies because the quota was in place and would not have gotten admitted otherwise. Throughout the paper, we refer to teachers turning 60 as ‘retirement’.

²1 SD in the share of male (quota) teachers corresponds to 6.5 percentage points.

ing. We use records from the nationally-organized allocation of education slots after compulsory schooling, for which pupils can put in up to five preferred institution choices. We find that male quota teachers have important effects at this pivotal moment: Pupils exposed to a higher share of male quota teachers are more likely to directly apply to continued education. As pupils apply more in line with their academic abilities, they are more likely to obtain one of their top two choices. These patterns translate into higher enrollment rates in post-compulsory education at age 16.

A central question that arises from our results is through which characteristics quota men – relative to marginal female teachers pushed out by the quota – make a difference. First, via a same-gender role model channel, male quota teachers could raise specifically boys' aspirations and achievement, thus helping to close academic achievement gaps between male and female pupils. However, adding more male role models for boys with a quota implies that girls will lose female examples to aspire to, potentially making them worse off. Examining results by pupil gender, we can rule out that girls are negatively impacted by the policy. Further, we do not find evidence for a role model channel that would purely operate through male teachers setting an example for boys via same-gender identity: Boys' educational attainment is not more affected from exposure to male quota teachers relative to girls', and none of the other main effects differ systematically by pupil gender.

Second, quota men could inspire pupils to pursue different educational fields. Our estimates indicate that pupils move away from more gender-neutral education choices and become more likely to choose a STEM (Science, Technology, Engineering, and Mathematics) field. We also examine whether exposure to more male quota teachers inspires boys to take up education related fields themselves. However, we find that pupils of either gender are not more likely to have chosen education-related or teaching fields by age 25.

Third, complementarities between male and female teachers (i.e. by specializing according to comparative advantage) could result in better outcomes for all pupils. The Finnish primary school system is characterized by extensive collaboration between teacher colleagues, both in school-wide curricula design and preparation of classes, as well as in actual teaching. Our analysis of the role of complementarities between male and female teachers estimates separate effects depending on the gender composition of the local teacher team. We find that the benefits of adding an additional male teacher are similar in magnitude between places with few male teachers and places where the share of men among colleagues is already high. However, a lack of precision prevents us from reaching decisive conclusions about whether our results are driven by quota men having inherently higher teaching ability than marginal women, or whether complementarities make teacher teams more productive.

We posit that the evidence in our setting is consistent with male quota teachers contributing positive qualities to the school environment that are not sufficiently captured by the selection criteria in absence of the quota. We document that the first order effects of the misalignment between these criteria and male quota teachers' effectiveness on the job dwarf any same-gender role model effects. While the quota thus neither closed educational attainment gaps between

male and female pupils, nor mitigated the gender-segregation of teaching fields in the long term, it succeeded in selecting male teachers with valuable characteristics, resulting in better outcomes for male and female pupils.

This study makes two main contributions. First, by examining the efficiency effects of a quota, we relate to recent work on affirmative action in university admissions documenting that marginal admits benefit similarly from access to selective colleges in the United States relative to marginal candidates pushed out (Bleemer, 2021b; Bleemer, 2021a; Black et al., 2020). Empirical evidence on how quotas specifically impact output-related measures has almost exclusively focused on quotas for women in board rooms, documenting negative or neutral effects on firm performance in the short run (Ahern and Dittmar, 2012; Matsa and Miller, 2013; Eckbo et al., 2021; Ferrari et al., 2021). We contribute to these papers by cleanly documenting that a quota – applied at university entry – improves output in the relevant sector in the long run. Our results also highlight a broader point, further illustrated in our conceptual framework: Selection of candidates based on academic scores and interviews, among the most widely used methods to assess applicants, can miss out on important dimensions of talent. A quota can mitigate such misalignment in settings when admissions criteria are imperfect predictors of effectiveness on the job.

Second, we shed light on the channels through which male quota teachers have a positive impact on pupils. Quasi-experimental studies studying the role of teacher gender have sought to explain effects via same-identity role model channels, such that a same-identity teacher affects academic performance (Dee, 2007; Antecol et al., 2015; Lim and Meer, 2017; Carrell et al., 2010). Work on targeted role model interventions has documented positive effects for female minority students (Porter and Serra, 2019; Breda et al., 2018; Kofoed et al., 2019). A key advantage of our study is that we can examine whether shifting the gender composition of an entire occupation via a quota has impacts on pupils via same-identity role model channels. We can thus address pressing policy questions regarding a quota’s potential to change the gender-segregation of occupation categories for future generations, with pupils in our setting being directly exposed to an occupation that is diversified via a quota.

Shedding light on how trade-offs related to equitable representation targets materialize by assessing their effects on productivity is important – especially so at a time at which affirmative action policies are under scrutiny. While many countries around the world are aiming to further diversify occupation categories (UN, 2019; Long, 2019), there is also significant push back in other settings. Universities in the United States and elsewhere are facing increasing judicial challenges for admission policies that embrace broader measures of academic preparedness (Leman, 2021; Dhume, 2019). Our results suggest that carefully considering the correlates of ability and minority group status in selection processes provides a promising avenue to increase both equitable representation and economic efficiency.

The paper is structured as follows: The next section details the Finnish education and teacher training system, and examines the quota reform as well as related literature in more depth. We outline a brief conceptual framework in section 3 to show more formally under which conditions introducing a quota would be more costly or lead to positive effects on output. Section 4 explains

our data sources and sample, followed by the empirical design in section 5. In section 6, we first examine the effects of the quota on teacher gender composition at the municipal level, before turning to a pupil-based panel. We document mechanisms in section 7 and robustness checks in section 8. The final section concludes.

2 Context

2.1 Primary school teachers in Finland

Finland has been among the top scoring countries for multiple rounds of international student assessments, leading to considerable international attention paired with efforts to adopt best practices from the Finnish education and teacher training system (Malinen et al., 2012; Niemi et al., 2016). Finland prides itself in having an equitable school system that aims at equalizing opportunities (Sahlberg, 2021).

Due to being one of the most competitive degrees in university admissions, primary school teachers enjoy high social status (Finnish National Agency for Education, 2018). While salaries are on par with OECD average, active teaching hours are comparatively low (Sahlberg, 2021). Primary school teachers are municipal employees who are hired by local schools, and are part of a powerful teacher union that sets both salary schedules, and – for the relevant period in this study – a retirement age of 60 for primary school teachers (Kivinen and Rinne, 1994; Valtiokonttori, 1988). A national curriculum outlines broad learning goals and teachers within and across schools collaborate in designing detailed learning plans under the supervision of municipal education authorities (Sahlberg, 2021; Sahlberg et al., 2019).

In contrast to the United States, primary school teachers may spend several years with one cohort of pupils as their main classroom teacher covering all subjects. However, primary school teachers are also actively embedded in their work environment through extensive collaboration with their colleagues, both in curriculum design, preparing lessons and school wide activities, as well as in active teaching (Sahlberg, 2021).

Pupils in our setting are thus experiencing and interacting regularly with the teacher body of their entire school. Conducting the analysis at the municipal level takes into account any spill-overs that arise from teachers collaborating within and across schools.³

2.2 Primary school teacher training and the quota reform

The first teacher training institutes in Finland were founded in the mid-1800s, and offered training separate by gender. In 1881, new education decrees allowed for co-education for children attending municipal primary schools as long as sufficient instruction in handicrafts could be guaranteed, de facto leading to “differentiation between male and female elementary school teachers and a quota system in teacher training” (Sysiharju, 1987). While the number of primary school teach-

³The median population size of the 461 municipalities in our sample is 5000 inhabitants. See also section 4.

ers in the first half of the twentieth century ballooned from 6,800 to 25,000 from the 1920s to the late 1960s, the share of male primary teachers remained stable at 41% (Sysiharju, 1987).

In the context of educational reforms in the 1970s, primary teacher education was transferred to universities and elevated to a master's level degree at the end of the same decade (Niemi et al., 2016). With an acceptance rate of about 10%, primary school teaching has been and still is among the most competitive degrees in the country and applicants often apply multiple years in a row until they are successfully admitted (Tirri, 2014; Uusiautti and Määttä, 2013).

Admissions throughout our study period closely followed the main principles established in those reforms, including that “the Ministry of Education maintained the sex quota system for the training of classroom teachers” (Sysiharju, 1987): In a first step, applicants were ranked in a centralized system according to a score that mainly considered candidates' grades in the matriculation exam (the nationally graded high school exit exam) with a few additional points given for candidates' extra-curricular activities. The highest ranked candidates were invited to an in-person second round (Uusiautti, Määttä, et al., 2013). In this second step of the selection process, candidates' teaching qualities were evaluated independently by a faculty board through an extensive host of exercises, including (among others) a live teaching exercise in front of real pupils, a pedagogical analysis of this practice lesson, and in-depth interviews (Räihä, 2010; Uusiautti, Määttä, et al., 2013). The highest ranked candidates in the second step were admitted to study primary teacher education according to the number of available study slots. Within this process, the Ministry of Education jointly with the education departments ensured that around 40% of candidates invited to the second round were men (Liimatainen, 2002). Documentary evidence on how strongly the universities were constrained in their final admission decisions for the decentralized second round is somewhat inconclusive (Räihä, 2010; Liimatainen, 2002). However, aggregate statistics imply that the general gender guidelines issued by the Ministry resulted in the desired gender mix of primary teachers: About 40% of active primary school teachers in the country were male until the mid-1980s (Sysiharju, 1987).⁴

The quota was abolished for the cohort applying to university in the fall of 1989 (thus graduating from primary school teacher studies in 1994), as it was not in compliance with a broad anti-discrimination law passed by parliament in 1987 (Tasa-Arvovaltuutetu, 1987). With the entry cohort of 1989, the share of men among candidates being invited to the second selection step dropped to 20% (Liimatainen, 2002). Since the quota's lifting, politicians and the general public have repeatedly argued for the quota's reinstatement, motivated by the fact that boys are increasingly lagging behind academically and that a growing number of children raised by single mothers may lack a father figure (Etelä Suomen Sanomat, 1988; Liiten, 2012).

We cannot directly observe how the quota and its lifting affected the gender composition of

⁴It is difficult to find statistics on pass rates and scores for the second step of the selection process for this time period. Uusiautti and Määttä (2013) cite a statistic from the University of Lapland in 1978, where about three applicants were invited per available study slot. In light of the quota expiring, a working group of the Ministry of Education recommended universities to invite at least four candidates per available study slot for the second round to ensure enough diversity among selected teachers without the quota (Etelä Suomen Sanomat, 1988). Mankki et al. (2020) examine scores received in the second step of the selection process in more recent years (after the quota), and show that male candidates receive higher scores than women.

admits as data on university applicants at that time were not recorded. Figure 1 therefore shows a proxy measure based on active primary school teachers in our sample to illustrate how the share of men among cohorts of incoming primary school teachers changed over time. We plot the share of men among those who ever work as a primary school teacher against the year of their last attempt at the matriculation exam that qualifies students for university studies. Since students can repeat the exam if they want to increase their score, the year in which they last took the exam serves as the closest proxy for when they start university studies: Anyone taking the exam in and after 1989 will with certainty have studied under the non-quota application regime. While the measure presented here only includes students who end up working as a primary school teacher, we can still observe a sharp and sudden drop of about 15 percentage points in the share of male teachers among matriculation exam cohorts.⁵

As the quota did not only change the gender composition of incoming teachers but also advantaged academically lower scoring men, Figure 2 plots future teachers' national percentile rank in the matriculation exam for the first attempt of the exam, against the last year in which they ever took this exam. We use the average national percentile score across all subjects for the *first* time that future teachers took the exam in order to get at a measure of inherent ability that is not influenced by repeated test taking. We plot this percentile rank against the date of their *last* exam to most closely approximate the point of entry to university studies.⁶ While the quota was in place, men on average scored about 10 percentiles lower. Once the quota was lifted, the average score among male teachers increased a bit, consistent with universities no longer admitting relatively lower scoring male applicants. We will return both to the changes in primary teacher gender composition and academic scores more formally in section 6.1.

Teacher gender in our setting is correlated with a bundle of other characteristics that may matter for teaching. Table 1 presents summary statistics on male and female teachers who are active in the profession before the lifting of the quota (i.e. before 1994 as the year in which the first non-quota cohort graduates from teacher studies), and thereafter. In Panel A, we can observe that male teachers are slightly more likely to come from rural areas and to live in their region and municipality of birth when compared to female teachers. Regarding educational trajectories in Panel B, there is no difference in having obtained a high school degree and being a certified teacher, but male teachers on average are a bit older both when finishing high school and when being awarded their teaching degree. In Panel C, statistics on the matriculation exam show no difference in having passed the exam, but again illustrate that male teachers perform much lower, even when considering the best exam take for repeated attempts. High school students had some flexibility to choose either mathematics or a combination of other natural and social sciences ("Reaali") in the matriculation exam. Male teachers are about 9 percentage points more likely to have taken the mathematics exam compared to female teachers, and 10 percentage points more

⁵Notice that the gradual drop before 1989 is consistent with a setting in which students apply multiple years in a row. We can only assess whether the quota was binding in this indirect way. While the lifting of the quota was widely discussed in policy and media reports at the time, we have found no documentary evidence that either application numbers or the composition of applicants would have drastically changed with the lifting of the quota.

⁶See also Appendix Figure A1 for the distribution of percentile ranks.

likely to have chosen advanced level mathematics rather than the basic level exam.⁷

2.3 Related literature

We contribute to two large branches of literature. First, we contribute to a large literature that has examined questions regarding the impacts of affirmative action policies on representation, quality and potential mismatch of marginal candidates. Studies of affirmative action policies have largely used different policies in the context of university admissions, most of them in the United States. Empirical evidence on quota policies, a subset of affirmative action policies which prescribe a fixed number or share of slots for a particular group, has to date almost exclusively examined two specific settings, both regarding female representation: quotas for board rooms in firms, and quotas in the context of political leadership.

A large body of work has documented that affirmative action policies succeed in raising representation for their intended beneficiaries from underrepresented minority (URM) groups (Bertrand et al., 2010; Yagan, 2016; Bleemer, 2021b; Bleemer, 2021a), but it has been a more contested issue whether lower levels of academic preparedness result in a mismatch of URM candidates to an environment that may be too demanding (Arcidiacono and Lovenheim, 2016). Recent quasi-experimental work on affirmative action at state flagship colleges in the United States suggests that these policies benefit their target group as intended and do not change outcomes for marginal students who are crowded out, rendering such policies both equity and efficiency enhancing on the margin (Bleemer, 2021a; Black et al., 2020; Bleemer, 2021b). In a similar vein, studies on quotas for female politicians have documented that ‘mediocre men’ are replaced with more highly qualified women in Swedish and Italian politics (Besley et al., 2017; Baltrunaite et al., 2014).⁸

Questions on whether affirmative action policies affect proxies for output have only been examined in the context of quotas. Survey-based evidence from a quota rule for female village heads in India documents that female leaders invest more in public goods favored by female voters, but these findings do not necessarily imply that female quota politicians are more efficient in delivering public goods overall (Chattopadhyay and Duflo, 2004).⁹ Evidence on how quotas for board rooms affect output related measures for firms has been inconclusive: The most frequently studied setting is Norway’s introduction of a 40% quota for female board members on publicly listed companies in the mid-2000s. Studies examining the quota’s effect on various measures of

⁷Each exam field and level of difficulty is graded on a curve within that group.

⁸In the context of the Norwegian board quotas, Bertrand et al. (2018) document that female board members hired due to the quota are more qualified relative to the average female board member before the quota took effect, but have lower levels of experience relative to the average male board room member.

⁹Chattopadhyay and Duflo (2004) specifically highlight that it is through the characteristic of being female herself that the leader’s preferences are more closely aligned with female constituents, thus moving the status quo to more closely reflect preferences of the median voter. Related studies are Beaman et al. (2012) and Beaman et al. (2009) who expand on the same setting and document that voters’ gender role attitudes regarding female leaders change in villages in which the quota rule assigned female chiefs twice in a row. These changes in attitudes drive increased representation of female politicians in the longer term (Beaman et al., 2009) and a reduction in gender gaps for adolescents’ aspirations and educational attainment, consistent with a role model channel (Beaman et al., 2012).

firm performance (Tobin's Q: Ahern and Dittmar, 2012; operating profits: Matsa and Miller, 2013; stock market returns: Eckbo et al., 2021) arrive at contradictory results that depend on the chosen counterfactual (see also Bertrand et al., 2018 for a review). Similarly, the direction of effects for analogous board quotas introduced in other European countries do not indicate a clear pattern.¹⁰ Two recent studies by “Can hiring quotas work? The effect of the Nitaqat program on the Saudi private sector” (n.d.) and Cortés et al. (2021) document negative effects on performance of a policy that required firms to hire native workers in Saudi Arabia.

In this paper, we can go one step further with respect to previous work on affirmative action and quota policies and cleanly document that preferential access to primary teacher studies does not just increase men's representation, but that their contributions to production in their industry lead to sizeable efficiency gains. We focus on a setting in which the entire composition of a broad and socially relevant occupation category is shifted by a quota rule and measures of output are readily observable in the long term. We further develop a conceptual framework to guide the analysis of how these efficiency gains may materialize despite male candidates' lower average quality in terms of academic achievement upon admission.

Second, we contribute to research that has been interested in examining the effects of teacher characteristics, and specifically teacher gender, on pupil outcomes. A large body of work has documented that measures of teacher value added, rather than certification or test scores (Kane et al., 2008; see Hanushek and Rivkin (2006) for a review), drive variation in pupil outcomes (Chetty et al., 2014; Rivkin et al., 2005). Several studies have documented that exposure to a same-gender or same-race teacher can improve academic performance (Dee, 2004; Dee, 2007; Lim and Meer, 2017, Carrell et al., 2010), and suggest a role model mechanism such that pupils become more motivated when paired with a same-identity teacher (Dee, 2005; Sansone, 2017).¹¹ An active literature has studied such role model effects also with respect to short and medium-run course enrollment in mathematically oriented fields for women (Carrell et al., 2010; Porter and Serra, 2019; Breda et al., 2018). These studies tend to document effects for specific underrepresented sub-groups, i.e. high achieving women attending a science track. Due to the level of detail and comprehensiveness of the Finnish register data, we can follow individuals throughout a substantial portion of their young adult life, and analyze their specialization choices in the long run. We add to prior studies by being able to observe a quota-induced shift in the gender composition of the entire occupation category of primary school teachers, thus being able to examine role-model effects in the light of quota policies.

¹⁰Results from Italy show no effect of a female quota on performance, but a positive reaction of markets to the quota-induced turnover of boards (Ferrari et al., 2021), while Comi et al. (2020) document opposite effects of gender quotas in Belgium and France (negative) versus Spain and Italy (positive).

¹¹Antecol et al. (2015) show that random exposure to a female primary school teacher with weak math background lowers girls' (but not boys') math performance, indicating that same-gender identity can also lead to undesired outcomes.

3 Conceptual framework

This section develops a conceptual framework assessing the trade-offs between teacher quality and gender representation. In our setting, the admissions office is the decision maker who would like to maximize future teacher ability. However, true teacher ability is unobserved by the admissions office so that it selects candidates based on scores.¹² We outline how a quota's effect on total candidate quality depends on the interplay between scores as the selection criterion and teacher ability: We first examine a benchmark case in which scores fully reflect teaching ability, such that a quota is costly. We then proceed to examine two cases in which the mapping of scores into ability is imperfect, such that a quota has the potential to be efficiency enhancing: We discuss a case where the mapping of scores is group-specific, and a case in which there exist complementarities in production between teachers of different genders. Finally, we embed same-identity role-model effects and show how a quota has differential impacts by pupil gender. We summarize these theoretical points by deriving testable predictions for the empirical part.

3.1 Set-up

Consider an admissions office that seeks to select a fixed mass of candidates C from a pool of applicants by considering their scores, s . Candidates belong to one of two groups j , with $j \in \{M, F\}$ for Male and Female, and are heterogeneous with respect to their score. Scores are defined on $[s, \bar{s}]$, the density of scores $h_j(s)$ is twice continuously differentiable, and we assume full support, $h_j(s) > 0$ on the relevant interval. We assume that the distribution of scores of the M group is first order stochastically dominated by the distribution of F scores to reflect the empirical fact that male applicants tend to have lower scores in our setting:

$$H_F(s) \leq H_M(s)$$

for all s , with strict inequality whenever $H_M > 0$ and $H_F < 1$. The mass of candidates of each group that is admitted above a cutoff score s^* is given by $M = \int_{s^*}^{\bar{s}} h_M(s)ds = 1 - H_M(s^*)$ and $F = \int_{s^*}^{\bar{s}} h_F(s)ds = 1 - H_F(s^*)$.

We further introduce a measure of candidates' teaching ability, a , that we will return to in more detail in iterations below. We define a welfare function W as the total teaching ability of admitted candidates for a given ability threshold, a^* :

$$W(a^*) = \int_{a^*}^{\bar{a}} a h_M(a)da + \int_{a^*}^{\bar{a}} a h_F(a)da \quad (1)$$

In our setting, the admissions office's aim is to pick the highest ability teachers, but since it can not observe a or is perhaps restricted to only consider s , it has to rely on candidates' scores as

¹²Without loss of generality, we make a simplification in the model relative to the actual selection process in our setting: We only look at a one-stage selection process based on scores (that can be any combination of academic score and evaluator score) to illustrate the main forces at play.

a proxy for ability.

Admissions without quota: The admissions office picks a threshold score s_j^* above which all candidates are admitted subject to a capacity constraint.¹³

$$\max_{s_M, s_F} \int_{s_M}^{\bar{s}} s h_M(s) ds + \int_{s_F}^{\bar{s}} s h_F(s) ds \quad (2)$$

$$s.t. \quad M + F = C$$

When maximizing total scores of admits, the optimal cutoff s_j^* is the same for both groups: $s_M^* = s_F^* = s^*$, resulting in the mass of admitted women outnumbering admitted men due to first order stochastic dominance.

Admissions with quota: Suppose we now introduce a quota rule that adds an additional constraint to the admissions office's optimization by requiring that at least mass q of students from group M be admitted. The admissions office then solves the problem in equation 2 with the additional constraint:

$$s.t. \quad M \geq q \quad (3)$$

When the quota constraint is binding, the admission cut-offs between groups diverge and the admissions office chooses optimal cutoffs that are group-specific:

$$s_M^*(q) = s_F^*(q) - \delta \quad (4)$$

where δ is the Lagrange multiplier of the quota constraint and indicates the shadow price of admitting a male candidate at the margin. The following iterations of the model briefly discuss how total teaching ability evaluated by W changes for different mappings of scores s into teaching ability a when the admissions office picks optimal cut-off scores, relative to admissions under full information.

3.2 Candidate choice when scores fully reflect ability

We start by evaluating a benchmark case: Scores fully reflect teaching ability, so that

$$a = s$$

¹³The admissions office's problem here is similar to Chan and Eyster (2003), who make the theoretical point that forbidding universities whose utility function contains an exogenous preference parameter for diversity from using race as a selection criteria will result in lower quality of admits. This results from the optimal admissions rule under race-blind admissions consisting in randomly selecting applicants above a lower cut-off score, whereas color-sighted admissions select the best scoring candidates within each group (see also Ray and Sethi, 2010). Ellison and Pathak (2021) bring the reasoning of Chan and Eyster (2003) to the data to evaluate the efficiency of a place-based affirmative action rule in two Chicago Public Schools. Instead of assuming a preference parameter for diversity, their model defines students' outcomes as a trade-off between an optimal level of school diversity and academic match. Our set-up does not assume a taste parameter for diversity.

In this case, requiring the admissions office via a quota to admit more men relative to the unconstrained optimization in equation 2 will result in total teaching ability of admits being lower under a quota: $W(s^*(q)) < W(s^*)$. This illustrates one of the main concerns frequently brought forward against quota rules: Requiring the admissions office to forgo its preferred allocation of slots will lower total candidate quality, as the ability of additional men admitted due to the quota is less than the ability of women who must be rejected to satisfy the quota:

$$\int_{s_M^*(q)}^{s^*} s h_M(s) ds < \int_{s^*}^{s_F^*(q)} s h_F(s) ds \quad (5)$$

3.3 Group-specific mapping of scores into ability

Consider now a case in which the association between scores and teaching ability is group-specific:

$$a = s + \alpha \mathbb{1}_M$$

with $\alpha > 0$, $\mathbb{1}_M$ an indicator function that denotes membership in group M , and density ρ such that $\rho(s + \alpha \mathbb{1}_M) = h(s)$. For any given teaching ability level a , the score of members of the M group is reduced by a penalty parameter α .¹⁴ In such a world, switching out a marginal female with a marginal male teacher who has the same score increases total teacher ability.

Full information: When evaluating total teaching ability of admits under full information, W takes into account men's true ability. Substituting for a with the above relation, the optimization problem when fully observing teacher ability becomes:

$$\max_{s_M, s_F} \int_{s_M}^{\bar{s}} (s + \alpha) \rho_M(s + \alpha) ds + \int_{s_F}^{\bar{s}} s \rho_F(s) ds \quad (6)$$

$$s.t. \quad M + F = C$$

The first order conditions under full information (FI) imply that the optimal cutoff scores in this case are such that:

$$s_M^{FI} = s_F^{FI} - \alpha$$

The marginal male admit here has a strictly lower score than the marginal female admit and the optimal allocation of slots fully takes into account that M group members' scores suffer a test score penalty α for any given ability level a .

Admissions Office: In contrast, the admissions office continues to select candidates based on scores alone (equation 2): $s_M^* = s_F^* = s^*$. In this case, it is the lack of differential score thresholds that is costly as the admissions office does not take into account men's score penalty,

¹⁴Note that richer models deliver a penalty parameter of this form. For example, when scores are a differentially noisy signal of ability for different groups, the conditional expectation of ability given score may take this form (Phelps, 1972; Aigner and Cain, 1977).

and $W(s^*) < W(s^{FI})$.

With a quota rule, the admissions office chooses $s_M^*(q) = s_F^*(q) - \delta$. The wedge between marginal male and female admission scores grows with the mass of male candidates required by the quota, and achieves the optimum under full information when the quota is set such that $\delta = \alpha$. This illustrates that the admissions office deviates further from the optimum under full information both when a quota under- as well as when it over-corrects for differences in scores: Total teaching ability will steadily decline with the mass of men required by the quota rule once $\delta > \alpha$, and will eventually yield an outcome worse than $W(s^*)$.

3.4 Candidate choice with complementarities

Even when scores fully reflect individual teacher ability, the existence of complementarities between M and F teachers can motivate differential treatment by group status. If the gains in total teacher ability from complementarities outweigh the costs in terms of individual scores, switching out marginal female with marginal male teachers will increase overall teacher quality, but with decreasing marginal returns. This could be the case if, for example, pupils are more motivated when exposed to same-gender teachers, or when diverse teams of male and female teachers perform better when designing school curricula.

We return to the assumption in the benchmark case that scores perfectly map into ability, $s = a$. We introduce complementarity in teaching ability with a production function V that exhibits positive cross-derivatives, and treats M and F candidates symmetrically:¹⁵

$$V = \sqrt{L_M L_F}$$

with $L_M = \int_{s_M}^{\bar{s}} s h_M(s) ds$ and $L_F = \int_{s_F}^{\bar{s}} s h_F(s) ds$ as total teacher ability for group M and F respectively. Under full information of V , the optimum equates the relative test score thresholds to the relative total ability of admitted candidates:

$$\frac{s_M^{FI}}{s_F^{FI}} = \frac{L_M}{L_F}$$

For a common threshold score $s_M^{FI} = s_F^{FI}$, it has to be that $L_M = L_F$, which is inconsistent with the assumption that $H_F(s)$ first order stochastically dominates $H_M(s)$ with strict inequality. The threshold for M must be lower, so that in the optimal allocation, $s_M^{FI} < s_F^{FI}$.

3.5 Same-gender role model effects

An interesting point to consider within this framework is how a quota would affect welfare separately by pupil gender due to the presence of same-gender role-model effects. To do so, we define total welfare as the sum of welfare for boy and girl pupils, and by adding a same-gender

¹⁵We focus here on homogeneity of degree 1, which implies that double the amount of teachers can teach double the amount of pupils, but any degree of homogeneity larger than zero yields the same conclusions

role-model constant r to teaching ability. Consider two groups of pupils with $p \in [b, g]$ where b stands for boy and g for girl pupils. We define teaching ability separately by pupil gender p :

$$a_p = s + r_p \mathbb{1}_{p=j}$$

with r_p a constant role model effect that depends on pupil gender and switches on whenever pupil and teacher gender coincide. In addition, we define W as consisting of total teaching ability for boys and girls. Substituting with the above equation for teaching ability and assuming equal shares of boy and girl pupils, we get:

$$W = \frac{1}{2}W_b + \frac{1}{2}W_g = \int_{s_M}^{\bar{s}} s h_M(s)ds + \int_{s_F}^{\bar{s}} s h_F(s)ds + \frac{1}{2}r M + \frac{1}{2}r F \quad (7)$$

Full information: Under full information, optimal cut-off scores at university admissions are:

$$s_M^{FI} = s_F^{FI} + \frac{1}{2}(r_g - r_b)$$

The relative magnitudes of r_g and r_b will determine the overall effect of a binding quota for male applicants. Irrespective of the overall effect, the impact of a quota will differ between boy and girl pupils: For girls, W_g declines both because of a decrease in teacher scores s and from loosing r_g for every female teacher being switched out with a male teacher. W_b instead experiences some gains from r_b . The impact of a quota that increases the number of male teachers at the expense of female teachers will thus always be less positive (or more negative) for girl pupils relative to boy pupils.

i) $\mathbf{r}_g = \mathbf{r}_b$: This reduces to the case discussed in section 3.2, such that a binding quota for male teachers will be costly in the aggregate.

ii) $\mathbf{r}_g < \mathbf{r}_b$: This reduces to the case in section 3.3, such that a binding quota for male teachers can be efficiency enhancing in the aggregate, and achieves the optimal allocation under full information whenever $\delta = \frac{1}{2}(r_g - r_b)$.

iii) $\mathbf{r}_g > \mathbf{r}_b$: In such a case, a binding quota will be costly both in terms of s and r .

The same reasoning applies as above when r is only beneficial up to a certain threshold (e.g. 50% of teachers of either gender). However, the relatively more negative effect for girls will be less pronounced compared to the cases discussed above.

3.6 Empirical predictions from conceptual framework

We therefore have several potential descriptions of the relationship between scores, output, and the effect of quotas.

Negative output effect of a quota: If test scores perfectly reflect future teacher ability, quotas will reduce output in the absence of complementarities. Our empirical set-up directly serves as a test of whether the quota was efficiency-enhancing by examining output in terms of

pupils' outcomes.

Positive output effect of a quota: If test scores imperfectly reflect teacher ability, so that men of a given test score tend to have higher ability than women, a quota may improve output so long as it is not too stringent. Complementarities may cause greater output from male teachers with lower test scores even if all components of ability are reflected in scores, but will do so with decreasing marginal returns.

Presence of same-gender role model effects: Irrespective of the impact of a quota in the aggregate, girl pupils will be more negatively/less positively affected from a male teacher quota relative to boys in the presence of same-gender role model effects. This is driven by boys gaining additional same-gender role-models when increasing the number of male teachers.

4 Data and sample

Our main data source is register data maintained by Statistics Finland which span the years 1988 - 2018, and contain detailed yearly information on all residents of Finland. We compile two main data sets that correspond to the respective parts of the analysis. For primary school teachers, we construct a panel of active primary school teachers from 1990 - 2000 for all individuals whose occupation at any point in time between 1990 - 2005 is classified as a primary school teacher by Statistics Finland's occupation classification system in the employment register. Since occupation categories are first available in 1990 and are not reported in every year, we use a combination of workplace, industry, salary, degree and career information to infer active teacher status in any given year (FOLK employment, basic, and degree). We can match teachers' matriculation exams scores and dates for all cohorts born after 1952 (YTL moduuli), but we unfortunately do not observe university enrollment or study progress for teachers as these registers were not maintained at the time.

For the pupils, we observe the universe of children living in Finland who turn seven years old (and therefore start school in that calendar year) between 1988-2000, reaching age 25 until 2018 as the last year of our data. We assign children to a municipality (and teacher gender composition during grades 1-6) based on their place of residence in the year in which they start school. We further match pupils to their parents which allows us to observe a rich host of variables related to families' socio-demographic characteristics at age seven (FOLK family). We merge the pupil cohorts to registers on post-compulsory education applications (EDU-THYR), registers that document enrollment in post-compulsory education (EDU-OPISK, only for school starting cohorts from 1990 onwards), as well as the population, degree and employment registers that are available on a yearly basis after age 16.

We measure all of the treatment variables at the municipal level as data to link pupils and teachers to classrooms or schools does not exist. As our main goal is to estimate the impact of a quota per se, and not the impact of having a teacher of a particular gender, aggregating the data to a level higher than the classroom is consistent with both the research question and a setting in which collegial collaboration is widely practiced. The median population size among

the 461 municipalities in our sample is 5000 inhabitants in 1990, with a median of 73 children by cohort in primary school. Appendix Figure A20 shows the CDF of the number of primary and middle schools combined across municipalities in the year 2005, as earlier or more detailed data was unobtainable. About 20% of municipalities have fewer than 5 primary and middle schools combined.

To comply with data disclosure regulations by Statistics Finland, we exclude municipalities that contain fewer than three teacher observations in a given year from our analysis. Once we move to a pupil level panel, we restrict the sample to municipality*year cells for which we are able to observe at least six teacher observations (i.e. the teaching staff for grades 1-6 of one school) to deal with noise arising from overlapping cohorts.

5 Empirical strategy

We want to study whether and how output is affected when the gender composition of teachers changes via a quota. Lifting the quota at the point of university admissions will impact the gender composition among active primary school teachers only gradually over time, but the changes in the flow of incoming teachers are sharp and immediate. In the estimation strategy, we therefore use shocks to the demand for new teachers in municipalities that arise from idiosyncratic local teacher retirement. Since teacher retirement could respond endogenously to the policy reform itself, we only use variation from teachers reaching the union mandated retirement age of 60. We use the term “retirement” exclusively to refer to teachers turning 60 throughout the paper.

Ideally, we would like to observe yearly pupil level outcomes and classroom specific links of pupils and teachers in order to differentiate between direct and indirect exposure effects, but such data does not exist. An ideal experiment, taking the aggregation level of our data as given, would consist in randomly removing some teachers from municipalities, and deciding with a coin flip whether replacement teachers are drawn either from a pool of only male quota teachers, or from a pool with only marginal female teachers.¹⁶

Our DiD-IV estimation strategy closely approximates this experiment, taking into account that changes in quota teachers materialize via the inflow of rookie teachers and that we cannot observe quota male and marginal female teachers in the data. Municipalities in our setting are randomly assigned quota men – and thus more male teachers in general – via the *timing* of their open positions arising from teacher retirement. We thus estimate a local average treatment effect for complier municipalities: Variation stems from those municipalities that via the timing of retirements are induced to hire more vs less quota men among their teachers. While this notion matters for assessing the external validity of results, we think that our estimates get us close to the policy relevant parameter of interest: What happens when we change the composition of an

¹⁶We label as “male quota teachers” those male teachers who were only able to enter primary teachers studies because the quota was in place and would not have gotten admitted otherwise. We refer to “marginal female teachers” to those female teachers who were able to be admitted to primary teacher studies once the quota was abolished and would not have gotten in if the quota were still in place.

occupation via a quota that operates through the inflow of incoming candidates?

Figure 3 outlines the timeline of our reform: The primary school teacher students who enter university before 1989 are selected via the quota rule. As the official time to complete the degree is five years, the quota and non-quota cohorts of new teachers will leave university around the year 1994 and will be hired by municipalities for their local schools. If municipalities have open positions during the time when quota cohorts enter the teacher market, they will be more likely to hire candidates from a pool with relatively more male rookie teachers compared to municipalities that have to fill open positions once new teacher cohorts selected without the quota are entering the teacher market.

5.1 Municipal level: Changes in teacher composition

We first document that local retirement interacted with the timing of abolishing the quota changes the local gender composition of teachers. Consider the following fixed effects specification:

$$\text{share male}_{mt} = \pi_0 + \pi_1 \text{total share } 60_{mt} + \pi_2 \mathbb{1}_{t=\text{post}} \text{total share } 60_{mt} + X_{mt}\delta + \eta_{rt} + \gamma_{mp} + \zeta_{mt} \quad (8)$$

with share male_{mt} the share of male teachers in municipality m in a given year t , and $\text{total share } 60_{mt}$ the cumulative teacher retirements in a municipality up to that point in time.¹⁷ The indicator function $\mathbb{1}_{t=\text{post}}$ switches on once non-quota teacher cohorts graduate and start entering the teacher market in 1994. The coefficient of interest, π_2 , measures how additional retirements in the post-quota period affect the share of local male teachers *relative* to when the quota was still in place. We add region-by-year fixed effects η_{rt} to control for time-varying shocks whose impacts may vary regionally, with a total of 19 regions comprising on average 24 municipalities. In addition, we can also add controls for time-varying municipal characteristics X_{mt} . The municipality-by-period fixed effects γ_{mp} ‘reset’ the measure of total retirements to zero once the post period starts to separately estimate how retirements affect the local share of male teachers in the post period.¹⁸

¹⁷The fixed effects specification of equation 8 uses the stock of the dependent variable (the share of male teachers) and the independent variable (the cumulative share retiring teachers over time). The corresponding first difference equation uses flows on both sides of the equation by regressing the year-on-year changes in the share of male teachers within municipality on the share retiring teachers in each year, dropping the municipal fixed effects:

$$\Delta \text{share male}_{mt} = \pi_0 + \pi_1 \text{share } 60_{mt} + \pi_2 \mathbb{1}_{t=\text{post}} \text{share } 60_{mt} + X_{mt}\delta + \eta_{rt} + \zeta_{mt} \quad (9)$$

We report first stage results for both equations, and use equation 9 when thinking in flows is more intuitive for some robustness checks on hiring patterns.

¹⁸The reset is necessary so as to properly net out any effect of the quota-period retirements from the post-quota estimate. The effect of retirements on the gender composition in the post should be independent of how much retirement the municipality faced in the quota period.

5.2 Pupil level: Does the quota shift in teacher gender affect outcomes?

Structural equation: Our main equation of interest is the following structural equation:

$$y_{im,t+x} = \beta_0 + \beta_1 \overline{\text{share male}}_{mt} + \beta_2 \overline{\text{total share 60}}_{mt} + X_i \delta + \gamma_m + \eta_{rt} + u_{imt} \quad (10)$$

with $y_{im,t+x}$ the outcome of interest at time $t+x$ for pupil i who at age seven lived in municipality m , and X_i individual level controls for socio-economic status, also measured at age seven.¹⁹ We add municipal fixed effects γ_m , as well as region-by-cohort fixed effects, η_{rt} . We are interested in how increasing the average share of male teachers via the quota affects pupils' outcomes, with $\overline{\text{share male}}_{mt}$ the average of the share of male teachers across the years we observe pupils in primary school.²⁰

Our empirical strategy isolates variation in the share of male quota teachers from gender changes in the inflow of recently graduated teachers that are caused by retirements. Rookie teachers may differ from older teachers along various dimensions: they have less experience, but they might also be differentially motivated to teach. We control for the overall potential share of rookie teachers a pupil is exposed to via retirements by controlling for the average aggregate share of teacher retirements during a pupils' time in primary school, $\overline{\text{total share 60}}_{mt}$. This measure is the average across all cumulative retirements a pupil experiences from grade 1-6, and we discuss it in more detail below. Note that it is possible that schools' hiring decisions, and thus the impact of being exposed to retirements, may change due to the quota. As such, our estimates measure the total effect of the policy that could include differential responses to retirement shocks. We elaborate on this in more detail in the robustness section 8, and do not find evidence that schools changed their practices over time.

First stage: We instrument for $\overline{\text{share male}}_{mt}$ with the following first stage equation on the pupil level that closely mimics the municipal level first stage in equation 8. Since every time period t corresponds to a particular cohort starting school at time t , we will refer to t as a cohort identifier in the following:

$$\overline{\text{share male}}_{mt} = \pi_0 + \pi_1 \overline{\text{total share 60}}_{mt} + \pi_2 \mathbb{1}_{t=\text{post}} \overline{\text{total share 60}}_{mt} + X_i \delta + \gamma_m + \eta_{rt} + \epsilon_{imt} \quad (11)$$

Variation in treatment intensity arises from how much teacher retirement different cohorts of pupils across different municipalities experience in the post-quota relative to the quota period. The coefficient of interest, π_2 , measures how the share of male teachers a pupil experiences is affected by retirements in the post-quota relative to the quota period. By measuring the differential impact of retirements, we compare the causal effect of being exposed to new teachers against the causal effect of being exposed to new teachers with a changed gender composition due

¹⁹The controls we include are pupil gender, language (Swedish, Finnish, other), foreign origin, single parent household, and highest level of education in the household (Compulsory, Secondary, Tertiary, n/a).

²⁰Our pupil panels spans 13 cohorts that are starting school in the years 1988-2000, and thus experience teachers who we can observe from 1990 - 2000. For some cohorts of pupils, we observe the teacher composition for each year that pupils are in school, while for others, we only know it for their starting or ending years. Appendix Figure A19 depicts the cohorts over time observed in our data.

to the lifting of the quota. In the structural equation, β_1 then measures the causal effect of being exposed to relatively more male teachers via incoming quota men. This relative comparison addresses exclusion restriction concerns that retirement triggered increases in rookie teachers matter for pupil outcomes.

We measure pupils exposure to retirements during their time in primary school, $\overline{\text{total share } 60_{mt}}$, by taking the average over the cumulative retirements a pupil is exposed to during their six grade levels g in primary school:

$$\overline{\text{total share } 60_{mt}} = \frac{1}{6} \sum_{g=1}^6 R_{mtg} \quad (12)$$

with $R_g = \text{share } 60_g + R_{g-1}$ and $R_1 = \text{share } 60_{-2} + \text{share } 60_{-1} + \text{share } 60_1$

For example, the retirement measure for grade 6 (R_6) adds retirements that occur just before a pupil enters grade 6 ($\text{share } 60_6$) to all retirements the pupil has experienced up to this point: $R_6 = \text{share } 60_6 + R_5$. R_1 considers all retirements up to two years before a pupil starts school. We construct $\overline{\text{total share } 60_{mt}}$ in this way to reflect the fact that retirements that happen later in the pupils' school career will have an impact on the teacher composition for relatively fewer years compared to retirements when pupils start school: Retirements that occur before a pupil enters grade 1 have the potential to change the gender composition, and thus the average share of male teachers, for all grades a pupil spends in primary school. In contrast, any retirements occurring just before a pupil enters grade 6 will affect the teacher composition only in their last year in school. In the empirical analysis, we report grade level results for the first stage that directly motivate the construction of this measure.

5.3 Discussion of identifying assumptions

We revisit explicit and implicit identifying assumptions of our setting in more depth. To start with, our identification strategy needs to satisfy the two main IV assumptions. Relevance requires that teacher retirements in the post-quota period decisively impact the local share of male teachers, which we can assess directly in the first stage regressions. The exclusion restriction, briefly touched on in the above, warrants more discussion: We require that teacher retirements affect pupils' outcomes only via changes in the share of male teachers, and thus changes in male quota teachers. However, retirements themselves, by triggering teacher turnover, may have a direct effect on pupils. We tackle this by measuring relative changes in outcomes between cohorts that experience similar exposure to retirements, but with different timing. The underlying assumptions here are twofold: First, we need to assume that there are no other policy changes that happen simultaneously with the quota that have effects on students *via the channel of retirements*. To the best of our knowledge, there are no such policies. Secondly, we assume that exiting patterns and hiring practices to replace retiring teachers do not differentially change as

a response to the quota.²¹ We test for such patterns in Section 8 and do not find evidence for differential changes in the post period.

Implicit in our empirical design is the further assumption that the local timing of retirements is idiosyncratic, and therefore uncorrelated with any other shocks that could affect pupil outcomes. We address such concerns by only using variation arising from teachers turning 60 (instead of actual exits), by controlling for a rich host of pupils' socio-economic characteristics at age 7, and by including region-by-cohort fixed effects. As such, we are only comparing cohorts in municipalities within the same region and year, with the notion that relevant economic shocks (in the past and currently) will similarly affect neighboring places.

Finally, while our regressions are measuring the effect of having more male quota teachers, we see teacher gender not just as a biological distinction, but as something that proxies for a bundle of characteristics that may differentiate quota male and marginal female teachers.

6 Main results

6.1 Municipal level: Effects on teacher gender composition

We start by documenting the effects on teacher gender composition at the municipal level after the quota was lifted. We first examine teacher exit patterns. Figure 4 plots the exit probability by age for all primary school teachers in our sample. We report the probability of a primary teacher not teaching at a given age, conditional on having been a teacher in the previous year. There are some exits around the time when teachers become mothers, but quite notably a large spike exactly at the union mandated retirement age of 60. In our estimation, we are only using variation from teacher exits that is due to teachers turning 60 years old. ²²

To illustrate the intuition of the first stage using the raw data, Figure 5 displays the relationship between teacher retirement in a municipality (on the horizontal axis) and changes in the share of male teachers by separately plotting the period in which quota cohorts enter the teacher market (1991-93) and a period of similar length in the post-quota period (1994-96). We can see that teacher retirement has a small positive effect on the local share of male teachers in the quota years. In the post-quota period, higher shares of teachers retiring are associated with substantial local drops in the share of male teachers.²³

Figure 6 formalizes this intuition by running the first stage equation 8 as an event study, estimating separate coefficients year-by-year, relative to 1993 as the baseline year. Teacher retirements in the years in which the quota was still in place do not differentially have an effect

²¹This includes the monotonicity assumption that rules out defiers in a LATE framework. In our case, these would be municipalities that would not want to hire male teachers while the quota is in place when facing retirements, but start hiring differentially more male teachers for retiring teachers in the post period.

²²Appendix B shows municipal level statistics on teachers turning 60. We also examine teachers' likelihood of changing jobs across municipalities in Appendix Figure A5. Less than 1% of teachers in the age bracket above 55 are changing the location of where they teach across all years of our panel.

²³Note that since our teacher panel spans 1990-2000, the first time we can calculate the share of teachers turning 60 that is relevant for re-hiring for the upcoming academic year is for 1991 (i.e. the 1991/92 academic school year)

on the local share of male teachers relative to the year 1993, while retirements in the post period lead to a sizeable drop of about 20 percentage points. Table 2 summarizes this result for both the first difference and fixed effects specifications, by bundling years into a quota and post-quota period. Results are quantitatively similar across specifications. While retirements in the pre-period have a small positive effect on the local share of male teachers, the coefficient of interest on retirements in the post-quota period consistently reports large drops. We assess potential negative weights arising from two-way fixed effects estimation in our setting in section 8 following De Chaisemartin and d'Haultfoeuille (2020).

The magnitude of reported coefficients corresponds to measuring what would happen if all teachers in a municipality were to retire in the post-quota period: In this scenario, the local share of male teachers would drop by about 17-22 percentage points. These magnitudes match the drop in incoming male teachers reported by the literature and observed in teacher graduates in Figure 1. We can re-scale this coefficient to reflect a more realistic retirement pattern: If 10% of local teachers reach age 60 in the post-quota period, this translates into a 2 percentage point drop in the share of male teachers, which corresponds to a 5.5% decrease over the mean in the baseline period.

6.2 Municipal level: Effects on teachers' academic ability

While the quota targeted the gender composition of incoming primary school teachers, it simultaneously affected overall academic ability among teachers by giving preferential access to men with lower academic scores on average. While we only observe matriculation exam scores for teachers born after 1952, we can report a first stage estimating the effect of teacher retirement on average academic scores of teachers at the municipal level using these cohorts.²⁴ We restrict the sample to those municipalities for which we observe at least one teacher with a score in the baseline period. In Table 3, we report the results across different fields of the matriculation exam, using teachers' score in their first attempt at the exam. Albeit noisily estimated, the coefficient for average scores in column 1 implies that retirements in the post period lead to an increase of about 1.25 percentile scores in the local teacher body, relative to the quota period. This magnitude is consistent with replacing approximately 20% of teachers with an on average 7-8 percentile point higher test score in the post period (see Figure 2).²⁵ Coefficients are of similar magnitudes and precision when looking separately at different fields of the matriculation exam in columns 2 - 4.

Insofar as one might think that academic test scores translate into actual teacher quality or ability, there is an indication for small increases in average local test scores. These are noisily estimated as we do not observe score data for the entire sample of teachers. These noisy and

²⁴We observe scores for roughly 59% of the total teacher sample. For all specifications in which we need to restrict the sample due to data availability, we also run the first stage regression to ensure comparability. Those coefficients are reported in Appendix Table A1.

²⁵The average decrease in test scores estimated for the quota period relative to the stock of teachers are also present in the raw data and represent a general downward trend in teacher test scores (Izadi, 2021).

small increases in scores accompany sizeable impacts on local teacher gender composition in the first stage. We next turn to examine how these changes affect pupils.

6.3 Pupils: Labor force and educational attachment at age 25

We next turn to our panel of pupils, spanning the cohorts that enter primary school between the years 1988 to 2000. We start by documenting the first stage relationship: Are children who experience more teacher retirement post-quota exposed to fewer male quota teachers? Our outcome here is the average share of male teachers across all of the six years a pupil spends in primary school.

Figure 7a shows the first stage results if we regress the average share of male teachers on the share of retirements pupils experience just before they start each grade level, starting up to two years before they enter school and until grade six.²⁶ Figure 7a depicts coefficients separately for the quota period (grey) and the post-quota period (green), while Figure 7b shows the effect of retirements in the post-quota period *relative* to the quota period. Teacher retirements in the early years of students' primary school time have a large and significant impact on the average share of male teachers pupils experience during their time in primary school. At higher grade levels, this effect gradually peters out. This pattern is as expected as it shows that retirements in early grades, which affect the teacher composition during the entire six years a pupil spends in primary school, matter more for explaining the exposure measure which averages the share of male teachers a pupil faces across their entire time in primary school. Similarly, retirements that happen just before a pupil enters grade six will only impact the share of male teachers for one year, and therefore contribute less to moving the average share of male teachers over all six years. This pattern, as explained in section 5.2, informs our construction of the instrument when bundling a pupil's exposure measure across all grades. We define a pupils' average total exposure to retirements as the cumulative share of teachers retiring in each grade level, which gives more weight to retirements that have the potential to change the teacher composition for a longer time.

In Table 4, columns 1-3 show results for the pupil level first stage. Due to the cumulative nature of the explanatory variable, we can interpret this coefficient as 'how much does the average share of male teachers change if all teachers were to retire just before a pupil starts school'. The magnitudes are therefore similar to the municipal level regressions: Pupils facing 10% of teachers retiring just before they start school are exposed to about 1.8 percentage points fewer male teachers.

Turning to outcomes, we examine pupils' labor market attachment at age 25 as reported to Statistics Finland in the last week of the calendar year. As many youths are still studying at this age, but are classified as employed due to part time work, we combine the categories of being a student and being employed into one measure that reflects not sitting idle. For this age group,

²⁶ Appendix Figure A19 gives a detailed overview over which cohorts are exposed to quota years in which grade levels.

this metric is considered relevant to measure the propensity to successfully integrate into the labor market (Eurostat, 2021; OECD, 2021). Columns 4-6 in Table 4 report reduced form, and columns 7-9 IV results: Being exposed to more quota teachers during primary school results in higher likelihood of being either employed or a student at age 25.

The coefficients report the effect size associated with an increase of male quota teachers from zero to all of the teaching staff being male quota teachers. To scale effect sizes to match a more realistic pattern, we can consider the impact of a 1 SD increase in the share of male (quota) teachers, which is around 0.065. For a 1 SD increase in the share of male (quota) teachers, pupils have a 0.03 percentage points increase in likelihood of working or studying, which corresponds to a 4% increase over the mean. Translated into standardized effect sizes (see the bottom row of Table 5), exposure to 1 SD higher share of male teachers during primary school leads to a .09 SD increased attachment to the labor/education market.²⁷

Figure 8a and the corresponding Table 5 report effects for our preferred specification (column 9 of Table 4) for the remaining, mutually exclusive labor market status categories. While we observe no effect on unemployment, pupils are somewhat less likely to be on a disability pension, and significantly less likely to be out of the labor force for reasons other than disability. We report reduced form estimates for all main results in Appendix section D.

Figure 8b and Appendix Table A7 show results by gender. Instead of splitting the sample, we run our main specification (Equation 10) and include separate treatment effects for boys and girls while estimating controls and fixed effects jointly. Results are qualitatively similar to splitting the sample, but less noisily estimated.²⁸ We further discuss and relate results by pupil gender to the conceptual framework in section 7.2.

Next, we turn to examine educational attainment at age 25. After compulsory education, the Finnish education system has two tiers: vocational and academic. Standard three year vocational degrees offer training in occupation-specific skills. In addition to working towards the completion of a basic vocational degree, pupils may take academic high school coursework that qualifies them to study a broader range of subjects at higher education institutions and adds an extra year to their study time. Alternatively, or in addition, pupils can also take further specialization training, that expands and deepens occupation-specific skills.²⁹ While students from the vocational track may qualify for specific fields of tertiary education at university, the typical study path for the tertiary level is at polytechnics. The academic path, on the other hand, leads from a three year high school degree to a Bachelor's degree (3 years) and a Master's degree

²⁷We can also ask how many pupils in a school this corresponds to. An increase in the share of male teachers of 0.065 corresponds roughly to switching out 1 in 15 teachers from marginal female to quota male at a local school. As the average class size is 20 pupils, this place would have a total of 300 pupils, and therefore about 9 pupils switch their labor market status.

²⁸Estimating heterogeneity by pupil gender requires taking a stance on how to think about common shocks that are absorbed by the municipality and cohort*region fixed effects. When estimating these fixed effects jointly, the underlying assumption is that we expect time-varying economic shocks to affect the choices of boys and girls to a similar extent. We also report split sample results for the main outcomes in Appendix F.

²⁹An example for a basic vocational degree is training to work in the vehicles sector which covers subjects from car sales to vehicle mechanics, while additional qualifications allow pupils to specialize e.g. in specific areas of vehicle repair.

(2 years) at university. Appendix Figure A17 shows the organization of the Finnish education system in detail.

Figure 9a and Table 6 present results for educational attainment by examining the highest degree achieved at age 25 using mutually exclusive education categories. We can see a shift towards higher attainment both in vocationally oriented as well as in academic education paths. As such, we observe a shift away from remaining with compulsory education or a standard three year vocational degree only, towards a “vocational plus degree”, defined as vocational degree holders with additional specialist or high school qualifications. A 1 SD increase in the share of male (quota) teachers makes pupils .09 SD more likely to shift towards such a higher skilled degree. Turning to academically oriented degrees, we similarly observe a shift away from high school degrees towards having completed a university bachelor level degree. Results by pupil gender are displayed in Figure 9b and Appendix Table A8.

We can also look at realized fertility up to age 26. In Finland, there is low prevalence of teenage pregnancies and the average age at first birth increased from 27.2 in 1995 to 29 in 2016 and is close to the OECD average (OECD, 2019). Consistent with our finding that pupils invest more in education and have a higher attachment to the labor force when exposed to more male quota teachers, we can document in Appendix C that female pupils are less likely to have given birth by age 26, which is indicative of delaying fertility.³⁰

7 Mechanisms

Where do these effects at age 25 stem from, and how would male quota teachers make a difference? This part first explores in more detail the step-by-step educational decisions that lead to the observed differences when pupils are young adults. We then examine how our empirical results tie back into the predictions of the conceptual framework: First, we discuss whether any of the main effects are driven by boy pupils benefiting more from male quota teachers due to the presence of same-identity role model effects. We then turn to examine if effects derive from male teachers inspiring pupils to pursue different educational fields, and relate these results to insights from the conceptual framework. Lastly, we try to differentiate between a mechanism where either male quota teachers make teacher teams more productive via complementarities, or where male quota teachers are of overall higher teaching ability than the marginal female teachers they replace.

7.1 Intermediate outcomes: Applications to post-compulsory education

In order to better understand where the long run effects measured at age 25 originate, we next examine application choices to higher education options that take place after compulsory

³⁰For male pupils there is a small increase in the likelihood of having a first child by age 26, but it is statistically not significant and economically small.

schooling at age 16.³¹ After primary school (grades 1-6) and middle school (grades 7-9), pupils in Finland have the option to apply to upper secondary education, which typically takes three years to complete, is provided free of charge, and is divided into a vocational and academic track. In grade 9, the final year of middle school, pupils apply for their desired institution, and in the case of the vocational track also their desired field. While further education is not mandatory after age 16, application rates for upper secondary degrees are very high with around 90% of a cohort applying in early spring of their final year in middle school. Raising completion rates of upper secondary education is a policy priority as a post-compulsory degree is deemed crucial for labor force attachment: Finns with only basic education are four times more likely to be out of the labor force, and have significantly lower employment rates in adulthood (Virtanen, 2016; Niemi et al., 2016).³²

In the centrally organized application process, each pupil can submit up to five choices for institution (and field), and a student proposed ranked choice algorithm allocates available study slots.³³ Institutions rank applicants based on grades and other qualifications such as extracurriculars. As applications take place before pupils obtain their final grades that are used to allocate slots, and with the popularity of institutions and fields varying over the years, students face uncertainty over whether they are able to obtain a study slot. The number of available slots per degree is centrally regulated and about 4% of a cohort end up without a study slot in the fall after finishing middle school.

Figure 10a and Table 8 report results on pupils' application timing and choices (Table 7 reports the first stage, reduced form and IV for the main outcome for this section). Having more male quota teachers makes pupils more likely to apply directly in their final year of middle school at age 16, and less likely to postpone applying to up to five years later.³⁴ We see no significant effect on never applying to upper secondary education. When considering the allocation of slots, we further observe that pupils are more likely to get one of their top two choices, while the effect of not getting any slot at all is muted. Consistent with Virtanen (2016), we find that these patterns translate into higher enrollment rates in upper secondary education in general, and significantly so in the year in which students turn 16. Figure 10b and Appendix Table A9 report heterogeneity by pupil gender, with coefficients not statistically different for any outcome.

Why are pupils who are exposed to more male quota teachers more successful in obtaining their preferred choice? We can check whether pupils apply more cautiously, with their main choice between aiming for an academic high school degree or a vocational training. We report

³¹Virtually everyone (99.7% of a cohort) successfully graduate from compulsory education (Virtanen, 2016). See Appendix Figure A17 for more details on the Finnish education system

³²Prior research with Finnish data has shown that the choices and slot allocations in upper secondary education can be pivotal: With an RDD design, Virtanen (2016) shows that failing to obtain a preferred choice or a study slot at all results in a lower probability of graduation. Virtanen (2016) also provides an excellent in-depth description of the allocation process of slots for upper secondary schooling.

³³For an infinite number of choices, the algorithm would be strategy proof. Since students can only submit five choices, some may choose to enter a 'safe' option to make sure they get a study spot.

³⁴With a very simple back-of-the-envelope calculation, the increase in the propensity to apply can explain close to a quarter of the labor force attachment effect in section 6.3 (the raw difference in labor force attachment for pupils who directly apply against those who don't is 25.4 percentage points).

effects in this part directly by pupil gender, as for these outcomes results differ significantly and overall effects mask more intricate patterns. Appendix Table A10 in Appendix E reports results. Male pupils are more likely to include any vocational training option among their choices (column 2), while refraining from applying exclusively to academic high schools (column 3). For the girls, while not statistically significant, the effect goes in the opposite direction. Overall, boys seem to become somewhat more cautious in their applications, and girls more confident. When examining for which track options pupils obtain a slot in columns 4–6, we see that the margin for boys shifts from not obtaining a slot at all (column 4) towards getting a vocational spot (column 5), while girls become more likely to obtain an academic spot (column 6) rather than a vocational one. Taken together, these results imply that having more male quota teachers makes pupils apply more in line with attainable options: Boys adjust their aspirations downwards, which prevents them from ending up without a slot at all, and girls correctly have high aspirations as they are more likely to get into academic high schools.

7.2 Role model effects

While the main effects clearly demonstrate that the overall impact of the quota was positive, boys should benefit more from having more male teachers relative to girls in the presence of same-gender role model effects (see section 3.5). This further raises the question whether the overall impact of the policy could mask that boys benefited while girls were made worse off.

As displayed in the figures and tables of our main results at age 16 and 25 by pupil gender, girls' outcomes are not negatively impacted from exposure to male quota teachers. We then test whether boys benefited more from male quota teachers: For educational outcomes at age 16 (Figure 10b), we cannot reject the null hypothesis of the coefficients being the same for boys and girls for any outcome at the 5% level, with the exception of remaining without a study slot (p-value of 0.017). While some coefficients differ significantly by pupil gender for highest degree achieved at age 25 (Figure 9b), these are the ones where boys are not benefiting as much as girls.³⁵ There are significant differences by pupil gender for our main labor market outcomes at age 25, with boys having better outcomes than girls. However, this pattern is quite sensitive to the choice of whether to estimate fixed effects jointly or separately by pupil gender. As shown in Appendix F, this gendered pattern reverses when estimating results in a split sample, and we cannot reject that coefficients are the same for boys and girls for those specifications.

Rather than providing a same-gender role model for boys, male teachers could also substitute for male role models at home for children growing up in single parent households (about 13% of the sample), of which most are headed by single mothers. With the caveat that heterogeneity along this dimension is not randomly assigned and may be correlated with other characteristics, in Appendix G we display effects by whether pupils live in a single parent household when starting primary school. While effect sizes are the same for outcomes at age 16, pupils growing

³⁵The results that are significantly different at the 5% level with girls better off are: compulsory education, and having a tertiary vocational, BA and MA degree.

up in single parent households have somewhat stronger benefits from exposure to male quota teachers in the longer run outcomes at age 25.

Taken together, we do not detect main effects that differ systematically by pupil gender. A same-gender role model channel that would make boys better off is thus not driving the positive impacts of the quota in the aggregate.

7.3 Education fields

We next turn to study whether exposure to more male quota teachers inspires pupils to pursue different education fields. The previous section highlighted that the main effects do not differ by pupil gender. However, a same-gender role model effect could also consist in male teachers setting an important example of men working in an occupation that is female dominated. As such, they may inspire primarily boy pupils to pursue a teaching-related field. Advocates of quotas often argue that temporary quota measures could be enough to inspire the next generation to pick less gender-stereotypical occupations.

On the other hand – and separate from a classical same-gender role model effect – male teachers could motivate pupils to pursue different education fields. This could be either via generally improving pupils' achievements or via male teachers' skills and motivation for particular subjects. As we have seen in section 2.2, male teachers are on average more likely to have chosen advanced math as one of their matriculation exam fields, and may thus be more skilled or motivated to teach mathematically oriented topics.

In order to investigate these hypotheses, we measure pupils' choice of education field at age 25. We classify their career choices via their education field rather than their occupation because many youths at this age are still studying. For each pupil in our sample, we pick the field of the highest degree acquired if they are no longer a student. For anyone who is still studying, we take the field of their current degree. We define fields as primarily female or male dominated based on the generation prior to our sample, i.e. the 13 cohorts who are seven years old during the years 1975-87. If either gender constitutes more than 40% within a field and degree level cell, we define the field as male or female leaning, and gender neutral otherwise.³⁶ This results in 30% of pupils being in "Male" fields, 43% in gender-neutral, and 27% in "Female" fields. We also report results on STEM and STEM-M (STEM plus Medical) fields as well as teaching-related fields in general and primary school teacher in particular.³⁷

Figure 11a and Table 9 report results on the choice of education field. The first three coefficients report results for primarily male, gender neutral and primarily female fields. We can observe a shift away from gender neutral fields towards both more male- and female-dominated

³⁶I.e. we define share female based separately for a vocational degree in business vs. an academic degree in business. For the group that has never finished a degree beyond compulsory education and is currently not a student (9.8% of the sample), we assign the gender share of compulsory education, which is categorized as a gender-neutral field based on the previous generation.

³⁷We define both academic and vocational degrees as STEM if the three-digit classification of Statistics Finland is one of the following fields: Agriculture (incl. Forestry and Fishery), Biology, Engineering, Environment, ICT, Mathematics and Statistics, Physical Sciences, Veterinary, and the 4-digit category related to Materials (glass, paper, plastic and wood). STEM-M in addition includes the 3-digit field Health.

fields, but these effects are muted. Turning to STEM and STEM-M, we observe that pupils are more likely to take up such fields when exposed to more male quota teachers, with effect sizes corresponding to a 0.08 and 0.09 SD increase for a 1 SD increase in the share of male quota teachers, respectively.

Figure 11b and Appendix Tables A11 and A12 show results separately by pupil gender.³⁸ For both boys and girls, we can observe a shift away from gender neutral fields towards both more male- and female-dominated fields, but only the coefficient of boys moving away from gender neutral fields is significant at a conventional level. In column 4 and 5, we observe coefficients that show a shift towards STEM fields when being exposed to male teachers. Regarding teaching fields overall and primary teacher education specifically, we fail to reject a null effect. The patterns outlined are similar when we control for level of education.

We can do a simple back-of-the-envelope calculation to understand how much of the labor market effects could be explained from these results: If we increase pupils exposure to quota men by .1, this would result in an increase of 0.06 of pupils switching into STEM fields. Pupils with a STEM field have a 5 percentage point higher attachment to the labor force (0.88 vs 0.83 for non-STEM pupils). Increasing the share in the population with a STEM field by 0.06 would thus result in a 0.003 increase in labor force attachment, or put differently, explain about 5.8% of the total increase in attachment measured in section 6.3.

The results for pupils' choice of field are thus somewhat indicative of both male and female pupils moving away from gender-neutral fields and becoming more inclined to pursue STEM oriented fields when exposed to more male quota teachers. As effects move in the same direction for both pupil genders and we do not find evidence for boys becoming more likely to take up education related fields, we again fail to establish support for same-gender role model channels.

7.4 Complementarities between male and female teachers

Based on the predictions outlined in the conceptual framework in section 3, we also try to distinguish whether our results are driven by complementarities between male and female teachers. We do this by assessing marginal returns to more male quota teachers along the distribution of the share of male teachers at baseline (i.e. in 1990): If male and female teachers are complements, adding an additional male teacher at a place with mostly female teachers should have larger marginal returns compared to adding an additional male teacher in an environment that is close to gender parity. We split the sample by the median of initial share of male teachers in a municipality. The first group has initially a low share of male teachers (on average 29% within the group), and the second group has a relatively higher share of male teachers (on average 43%).³⁹ Appendix H reports results: The estimated coefficients in both groups are similar, but

³⁸In all of the regressions on field choices, we do not estimate joint fixed effects for both genders, but report separate regressions by splitting the sample. We do this since for these gendered outcomes, the assumption that shocks would affect boys and girls similarly does not seem justified (i.e. a shock that raises demand for health care workers is likely to have quite different effects on young women vs. young men).

³⁹We can split the sample at other points in the distribution, with results qualitatively similar across different splits.

the standard errors are too large to draw decisive conclusions.⁴⁰ We can thus not convincingly distinguish whether we find positive effects in our setting because diversity itself makes teacher teams more productive, or because within the scope of the policy, quota men have higher inherent teaching ability than the marginal women they replace.

8 Robustness

8.1 Do schools change hiring practices due to the reform?

Our treatment coefficients measure the effect of the quota policy, and thus include any impacts that may be due to schools responding endogenously to the policy, for example by changing their hiring patterns and recruiting more experienced teachers in lieu of rookies. While this is not a direct threat to identification, assessing these aspects helps to understand the underlying drivers of our effects. We therefore examine whether any other aspects of local teacher composition changes in response to the reform. Table 10 reports first difference municipal regressions, with all specifications assessing changes in flows for consistency (equation 9). Our goal is to understand whether retirements that happen in the post-quota period differentially change proxies of teacher experience relative to retirements in the quota period.

We start by assessing the effect of teachers turning 60 on overall teachers leaving their current job in columns 1 and 2. The share of teachers turning 60 has almost a 1:1 impact on the share of teachers leaving, but not differentially so in the quota period. This effect is not driven by turnover of relatively younger teachers (column 2), and rather reinforces the observation that teachers reaching age 60 corresponds to actual exits from the teaching profession. In column 3, we examine how retirements affect the average age of the local teacher body. Retirements in general reduce the average age among local teachers by 16 years. Importantly, we do not detect a sizeable change in the post-quota period: Average age of teachers in response to retirements in the post period drops by an additional 1.3 years, which is not statistically significant and consistent with slightly gendered age profiles when entering the teaching profession observed in section 2.2. In the fourth column, we observe similar effect sizes for the average number of years since obtaining a teaching degree as a proxy for teaching experience. These results refer to composite changes and could just stem from teacher exit, therefore columns 5 and 6 examine as outcomes two different ways to calculate the share of first entrants to the teaching profession among newly arriving teachers in any given year and municipality.⁴¹ While noisily estimated, retirements in general result in a higher share of new entrants among newly arriving teachers at a municipality, but this does not change differentially in the post-quota period. Taken together,

⁴⁰Potential unobserved sorting of teachers into schools that deviates from the average municipal gender composition further makes our setting not an ideal case to test such a channel if collaboration matters more within than across schools.

⁴¹We define as a first entrant any teacher who is first observed in a given year as a teacher and is below the age of 28 (column 5) or below the age of 30 (column 6). We examine first entrants as a share of new arrivals since the truncated panel structure of our data results in differential likelihood of observing first entrants and new arrivals at any given point in time, but affects both variables similarly.

we fail to find corroborating evidence for changed re-hiring strategies as a response to the quota reform.

8.2 Teachers on parental leave

Apart from hiring patterns, the lifting the quota coincides with bringing more young female teachers to schools, who may have a higher propensity to go on leave when giving birth. The positive effects we detect from having more male quota teachers could then simply arise from pupils having less teacher turn-over, with high turn-over potentially having a negative effect on pupil outcomes. During the 1990s, Finland had 6.5 months of entirely shareable parental leave taking effect after 3 months of birth-related maternity leave (Kamerman and Moss, 2009).

To investigate whether any changes related to leave taking of teachers becoming mothers (or fathers) could affect pupils, we repeat the municipal first stage regressions. Table A18 (in Appendix I) shows that teachers turning 60 in the post period do not have a differential impact on either female or male teachers having a birth in their household. The last column documents that the share of a female teachers leaving the teacher force subsequent to becoming a mother is also not differentially affected by retirements in the post-quota period. In this set-up, the variation used stems from such patterns arising immediately as a response to teacher retirements. We therefore also document that, conditional on municipal and region-by-cohort fixed effects, higher exposure to female teachers having a newborn child does not matter for pupil outcomes (Appendix Table A19). We conclude that differential leave taking patterns due to maternity from more female teachers post-quota are unlikely to drive our results.

8.3 Heterogeneous treatment effects in two-way fixed effects designs

An active literature has documented that the treatment coefficient of a two-way fixed effects (TWFE) regression, $\hat{\beta}_{fe}$, reports a weighted sum of average treatment effects (ATE) (De Chaisemartin and d'Haultfoeuille, 2020; Arkhangelsky et al., 2021; Athey and Imbens, 2021; Sun and Abraham, 2020; Imai and Kim, 2021; Goodman-Bacon, 2021). If treatment effects are heterogeneous, it is possible that treated observations can receive negative weight such that the sign of the overall effect is of the opposite side than each of the individuals ATEs. Heterogeneous treatment effects in our setting could be an issue if, for example, municipalities that experience a retirement shock early in the post period systematically exhibit a treatment effect of the opposite sign (i.e. an increase in share male), and receive a negative weight.⁴² Negative weights by themselves are mechanically the product of any two-way fixed effects specification – it is in combination with heterogeneous treatment effects that problems with sign reversal may arise.

The TWFE literature to date has almost exclusively focused on staggered adoption designs with a binary treatment. An exception are De Chaisemartin and d'Haultfoeuille (2020) who also touch on a more general case where treatment is ordered and finite, such that there are

⁴²Due to for example municipal fixed effects differencing out a larger retirement shock later in the panel such that the earlier event is below the average level of retirements in this municipality.

observations that are untreated. De Chaisemartin and d'Haultfoeuille (2020) suggest sensitivity measures that are based on the variance of any weights associated with groups that have a treatment value that is strictly positive. In our setting, and somewhat contrary to the cases tackled in this literature to date, the treatment variable is infinite, and takes on the value of zero only for a very few extremely selected observations, which makes the suggested sensitivity measures in De Chaisemartin and d'Haultfoeuille (2020) not directly applicable.

Still, we can follow the reasoning of De Chaisemartin and d'Haultfoeuille, 2020 (also highlighted by Jakiela, 2021), to examine the weights attached to our municipality-by-year groups. Intuitively, groups with lower treatment values should be more likely to receive negative weights as their treatment assignment is below average. The weights derived in De Chaisemartin and d'Haultfoeuille (2020) are proportional to the residual from a regression of the treatment variable on the fixed effects. Assessing the sign of the residuals in our setting is informative about the sign of this weight. For equation 8, this corresponds to:

$$\text{total share 60 post}_{mt} = \beta_0 + \beta_1 \text{total share 60}_{mt} + \gamma_{mp} + \eta_t + \epsilon_{mt} \quad (13)$$

With $\text{total share 60 post}_{mt}$ the share of teachers turning 60 interacted with an indicator for the post period. Appendix Figure A11 plots the mean of binned residuals along the distribution of our treatment variable for equation 8, with colors indicating above (red) or below (blue) median values of treatment intensity (Appendix J). Reassuringly, the weights attached to the municipality-by-year groups follow a clear pattern where observations with below median values of treatment are the ones that on average receive negative weight.

We also probe whether treatment effects in our setting are likely to be heterogeneous across various dimensions. To this extent, we assess whether treatment effects are driven by particular years, municipalities, cohorts or levels of treatment assignment. Appendix Section K report leave-one-out specifications, with coefficients not sensitive to dropping particular groups at a time. We also examines whether treatment effects differ across different levels of retirement in the post period (see Appendix Figure A12). While we cannot rule out that there may be some heterogeneity in our estimated treatment effects, given the probing outlined in this section, we think it is unlikely to be sufficient to change the sign of our treatment coefficients.

9 Conclusion

In this paper, we document that a quota that advantaged academically lower scoring men to obtain a study slot for primary teacher education has positive effects on output as measured by their pupils' long run educational and labor market outcomes. We find that pupils who were exposed to a higher share of male quota teachers during their time in primary school are more likely to be either in employment or studying at age 25, and have higher educational attainment as measured by their highest degree achieved.

Using comprehensive register data, we trace these long term effects back to consequential

application patterns to post-compulsory education: Pupils exposed to a higher share of male quota teachers are more likely to apply to continue education directly after middle school, to obtain their preferred study slots and to enroll. We show that pupils of either gender apply more in line with their academic abilities, albeit along different margins. We do not find evidence that our main effects are more pronounced for male pupils, ruling out a same-gender role model channel as the main mechanism. We then examine whether more male quota teachers inspire pupils to pursue different educational fields and show that pupils of either gender are more likely to choose a STEM field, but boys in particular are not more likely to choose education or teaching related fields.

The male teacher quota thus did not have an impact along two essential dimensions frequently emphasized in policy debates: It did not contribute to reduce occupational segregation – one of the main drivers of raw gender wage gaps – for the future generation, as boys were not inspired to pick an education-related occupation when exposed to more male teachers via the quota. Neither did the quota contribute to close educational attainment gaps between girls and boys, as both pupil genders benefited equally from exposure to male quota teachers.

Instead, the quota in our setting fixed an inefficiency present in the selection process of teachers. Our results show that the quota succeeded in recruiting male teachers that contributed valuable qualities to the school environment within the parameters of the policy. A promising avenue for future research lies in more thoroughly disentangling whether increased representation affects efficiency via a channel of complementarities in team work, via channels of inherent candidate ability, or via a mix of both. A further limitation of our setting is that it explores a partial equilibrium, and we refer to prior (Hsieh et al., 2019; Bleemer, 2021b) and future research to gauge the general equilibrium consequences of such policies for the allocation of talent in the wider economy.

Our study directly speaks to concurrent policy issues on affirmative action and optimal selection of candidates and illustrates the importance of carefully considering the relationship between selection criteria and minority status. In settings where a main criterion for choosing candidates is more negatively correlated with a particular group status than that group's effectiveness on the job, representation targets can help to overcome such misalignment if the selection criteria themselves cannot be easily changed. Both in academia, with current experimentation on SAT requirements for US college applications, and in the private sector, where companies are starting to use balanced candidate lists, such avenues are increasingly being explored. Our results suggest that this may pay off not only in terms of achieving more equitable representation, but also in terms of economic efficiency.

Tables and Figures

Figure 1: Share male among primary school teachers by year of last matriculation exam

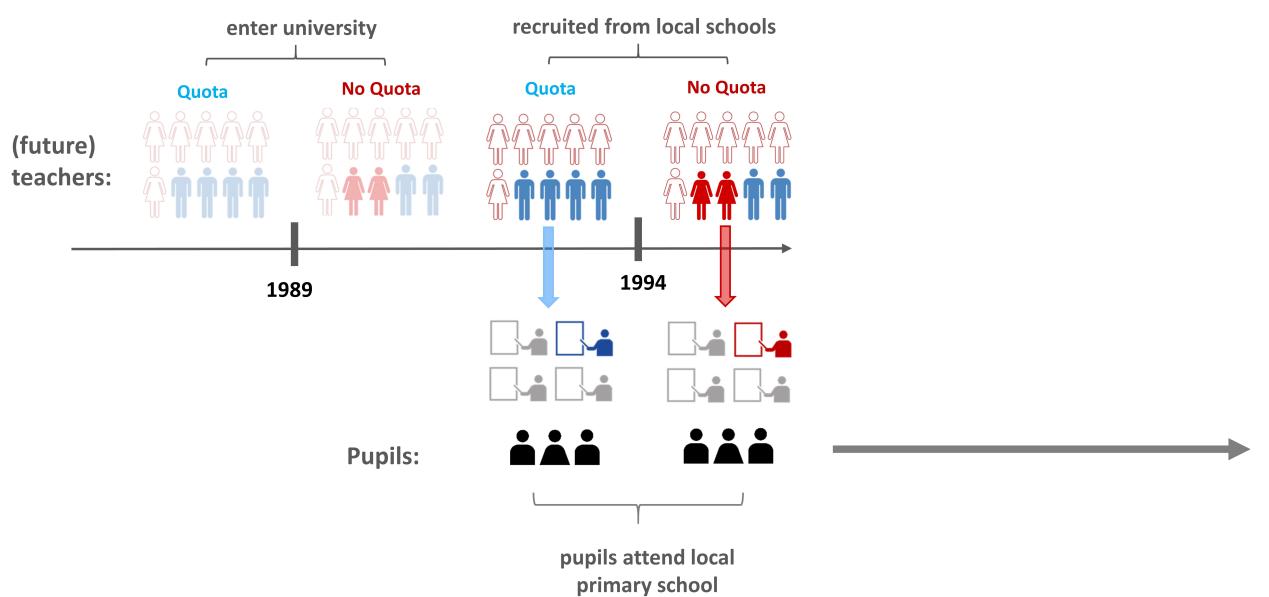

Note: Share male among active primary school teachers, by the last year in which they took the matriculation exam, which qualifies applicants for university admissions. Exam takers in 1989 (dashed grey line) and thereafter will have studied after the male quota was abolished. ([back](#))

Figure 2: Matriculation exam percentile rank among primary school teachers by year of last matriculation exam

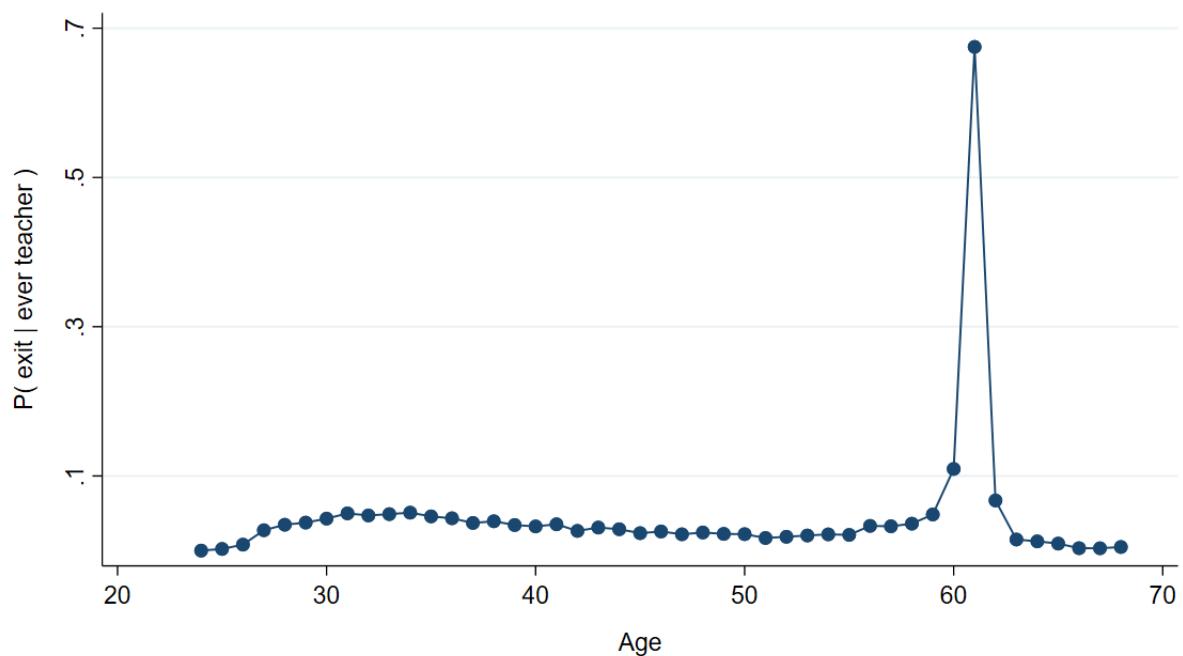

Note: National percentile rank across all subjects in the matriculation exam among primary school teachers, by gender and the last year in which they took the matriculation exam (qualifies applicants for university admissions). Exam takers in 1989 (dashed grey line) and thereafter will have studied after the male quota was abolished. Data on exam points for the year 1990 are missing, so that we cannot calculate the national distribution of scores according to percentiles for that year. Note that if the worst scorers are those that repeat the exam, this will bias the average scores in the years after 1990 upwards (the worst performers will not be counted in these averages as their scores are missing). We address this issue by also examining average grades, for which we have data in 1990. We can show that the pattern is similar and upward bias in the percentile scores after 1990 should be small. ([back](#))

Figure 3: Timeline of the reform

Note: Future primary school teachers enter university with the quota (pre-1989) and without the quota (1989 and thereafter), and graduate from the five year primary school teaching degree around the year 1994. Primary teacher graduates get hired by municipalities to teach in local schools. Pupils will experience differential exposure to quota teachers, described in detail in section 5 of the paper. ([back](#))

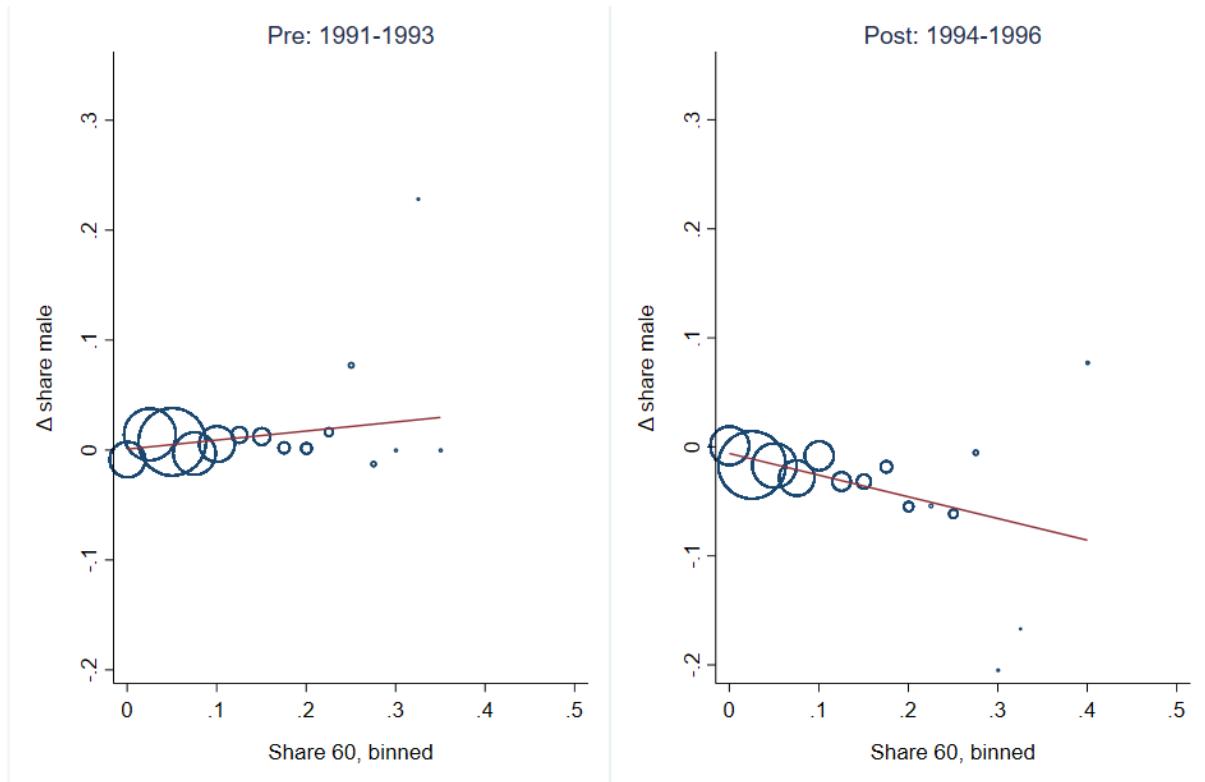

Figure 4: Probability of teacher exit by age

Note: Share of primary school teachers not working as a primary school teacher at a given age, conditional on having worked as a primary school teacher in the previous year. Data for all active primary school teachers in the years 1990-2000. Multiple exits per teacher possible.

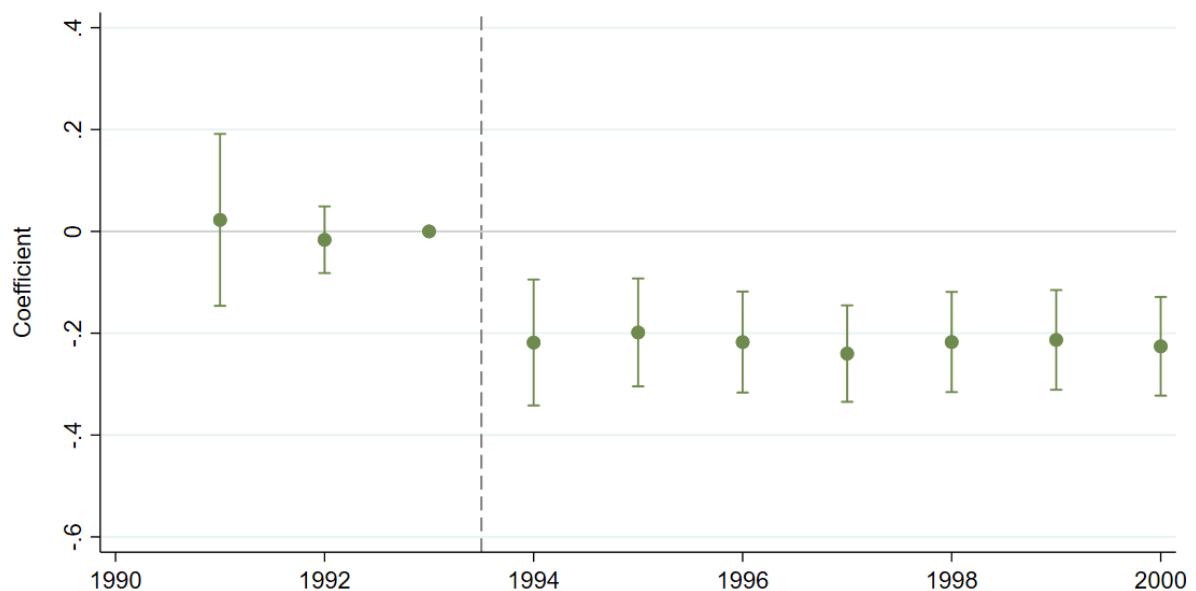

[\(back\)](#)

Figure 5: First stage intuition: Changes in share male teachers by local retirements, raw data

Note: Municipality level data, binned: Change in the share of male primary school teachers for a period of similar length in the quota (1991-93) and post-quota (1994-96) period against total share of teachers turning 60. Linear fit, weighted by the number of municipalities per bin.
[\(back\)](#)

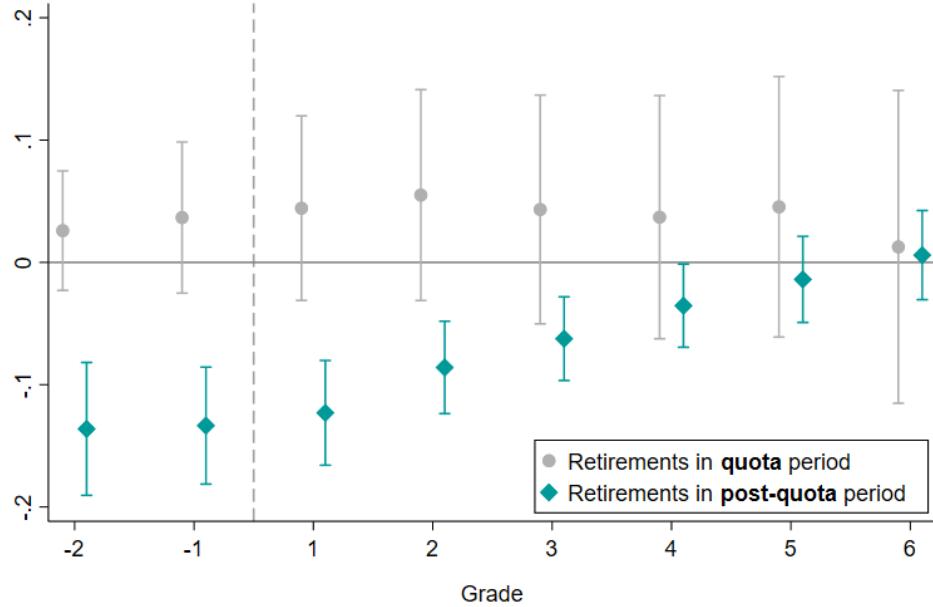

Figure 6: Municipal level first stage as event study

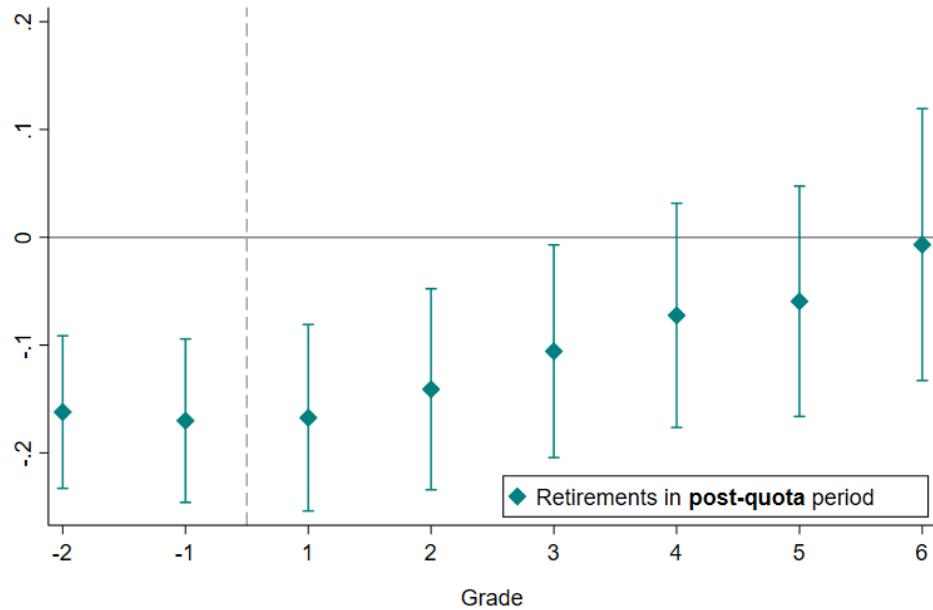

Note: Year-on-year estimates of π_2 for the fixed-effects first stage Equation 8, showing impact of primary teachers turning 60 on the local share of male teachers (relative to 1993). Standard errors clustered at the municipality level. Population weighted. [\(back\)](#)

Figure 7: First stage pupil level

(a) Separate estimation of quota and post-quota coefficients

(b) Post-quota (relative to quota coefficients)

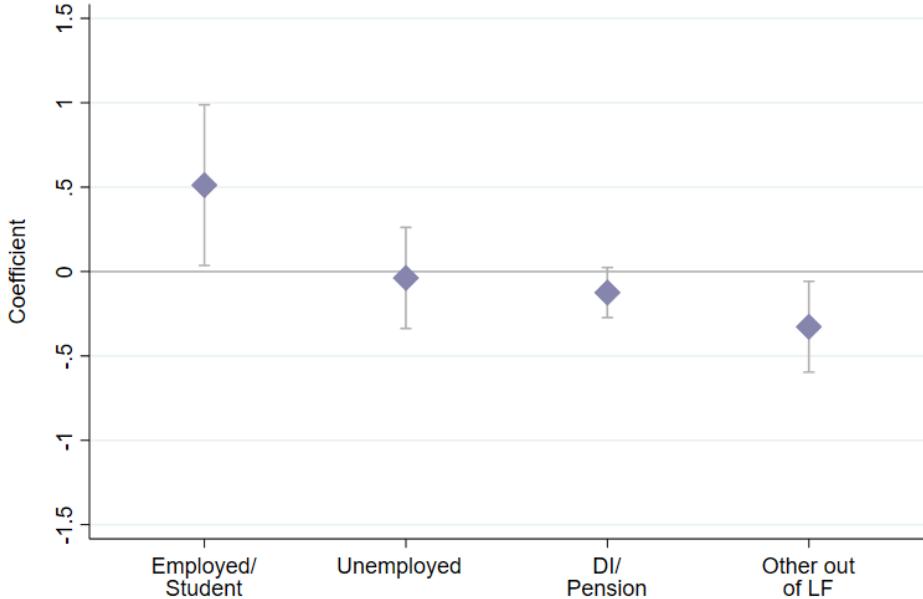

Note: Grade level estimation of pupil level first stage (c.f. Equation 11). Panel (a) estimates absolute coefficients for effect of retirements pupils experience in the quota and the post-quota period. Panel (b) depicts coefficients for the post-quota period *relative* to the quota period (i.e. it shows the difference between quota and post-quota estimates depicted in Panel (a)).

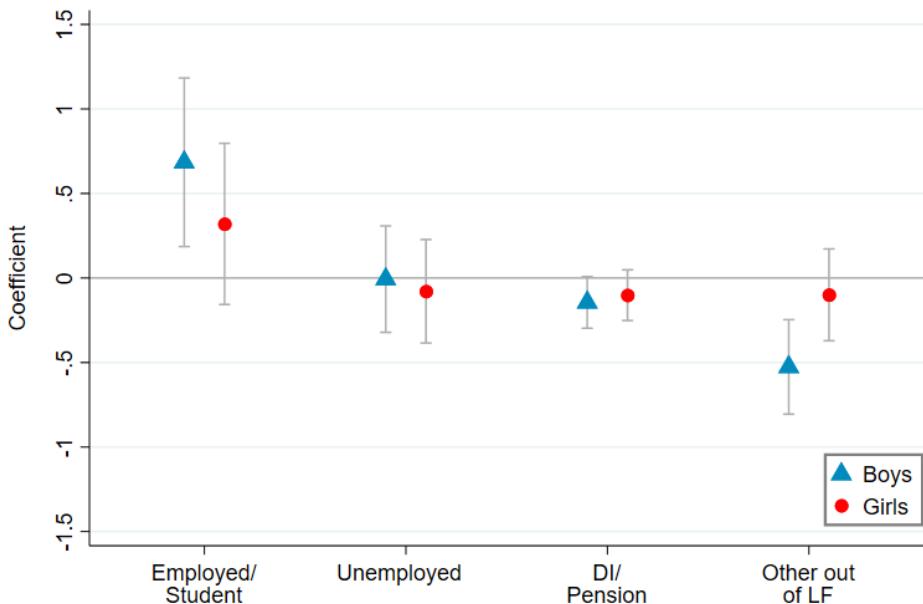

Outcome is the average share of male teachers a pupil is exposed to during their time in primary school (Grades 1-6). Individual level controls are measured at age 7 and include gender, language (SE/FI/other), foreign origin, single parent HH, highest level of education in HH. Standard errors clustered at the municipality level. ([back](#))

Figure 8

(a) Labor market outcomes at age 25

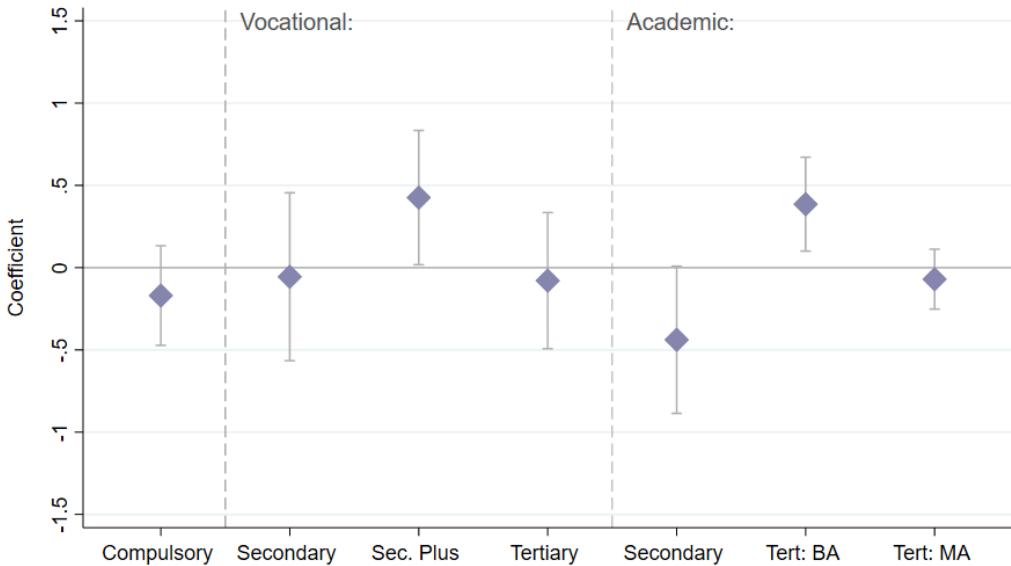

(b) By gender: Labor market outcomes at age 25

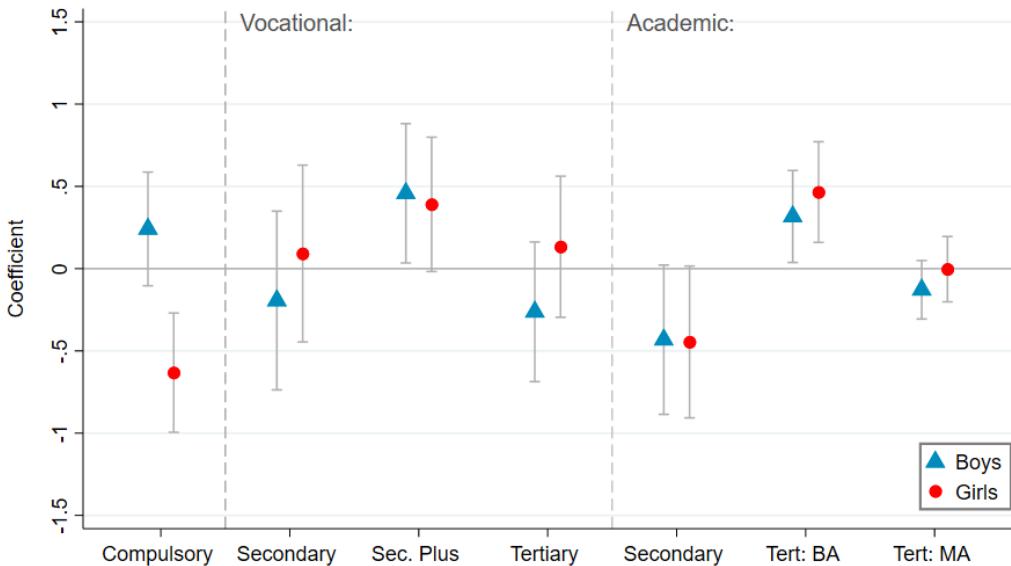

Note: IV estimates of Equation 10. Outcome: Mutually exclusive categories of labor market status in last week of the year in which pupils turn 25 years old. Individual level controls are measured at age 7 and include gender, language (SE/FI/other), foreign origin, single parent HH, highest level of education in HH. Standard errors clustered at the municipality level.
[\(back\)](#)

Figure 9

(a) Highest degree achieved at age 25

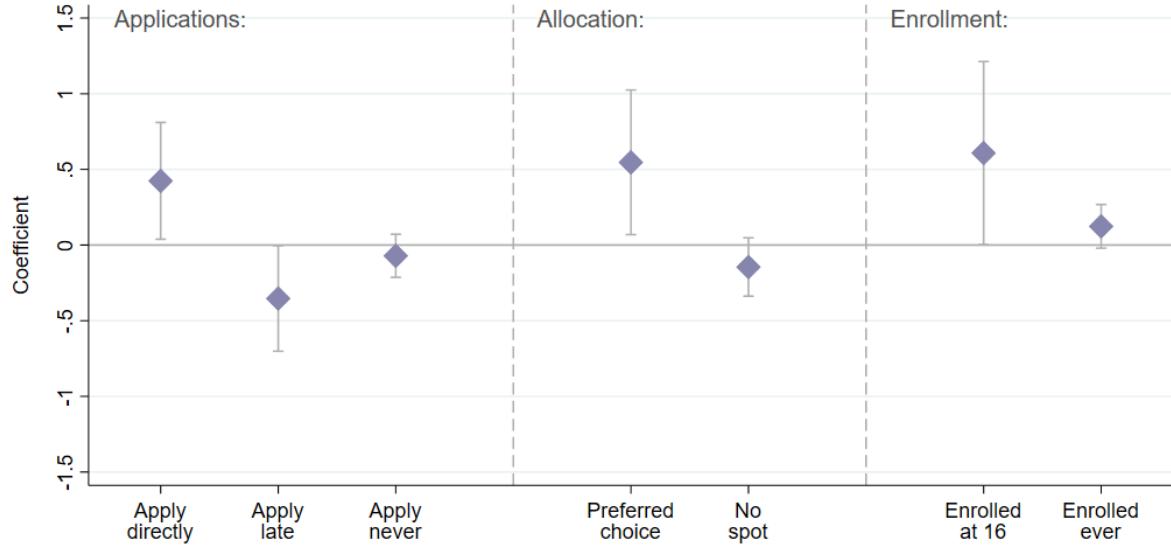

(b) By gender: Highest degree achieved at age 25

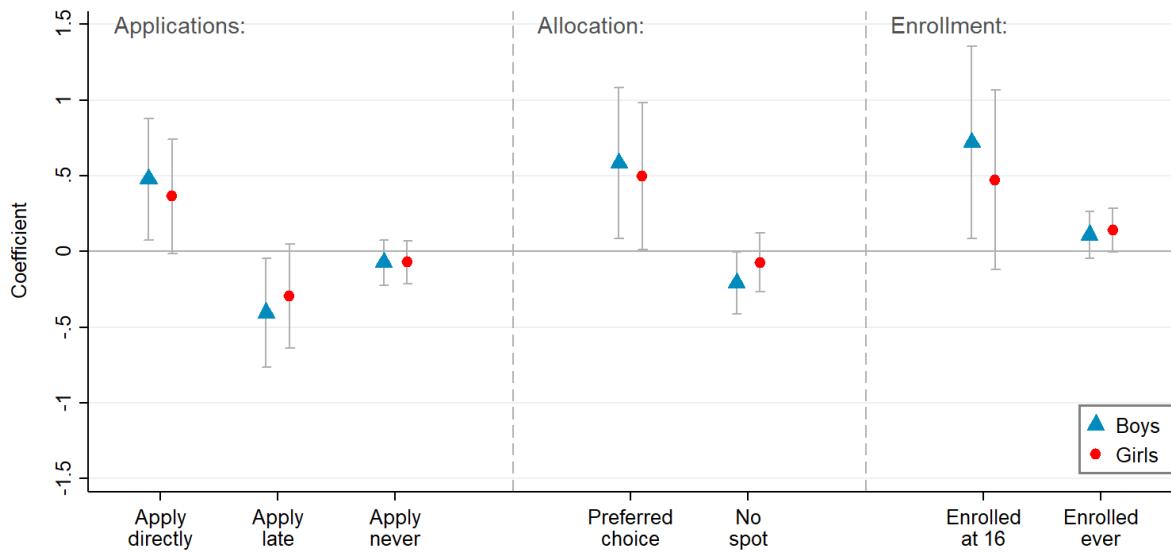

Note: IV estimates of Equation 10. Outcomes are mutually exclusive categories of pupils' highest degree achieved at age 25: Having only Compulsory education. For the Vocational track: Having a basic three year secondary degree (Secondary), having additional qualifications or high school coursework beyond a basic degree (Sec. Plus), having a tertiary degree from a polytechnic (Tertiary). For the Academic track: Having a three year high school degree (Secondary), having a three year university BA degree (Tert: BA), having a two year university MA degree (Tert: MA) or higher. Individual level controls are measured at age 7 and include gender, language (SE/FI/other), foreign origin, single parent HH, highest level of education in HH. Standard errors clustered at the municipality level. [\(back\)](#)

Figure 10

(a) Applications and enrollment for post-compulsory education

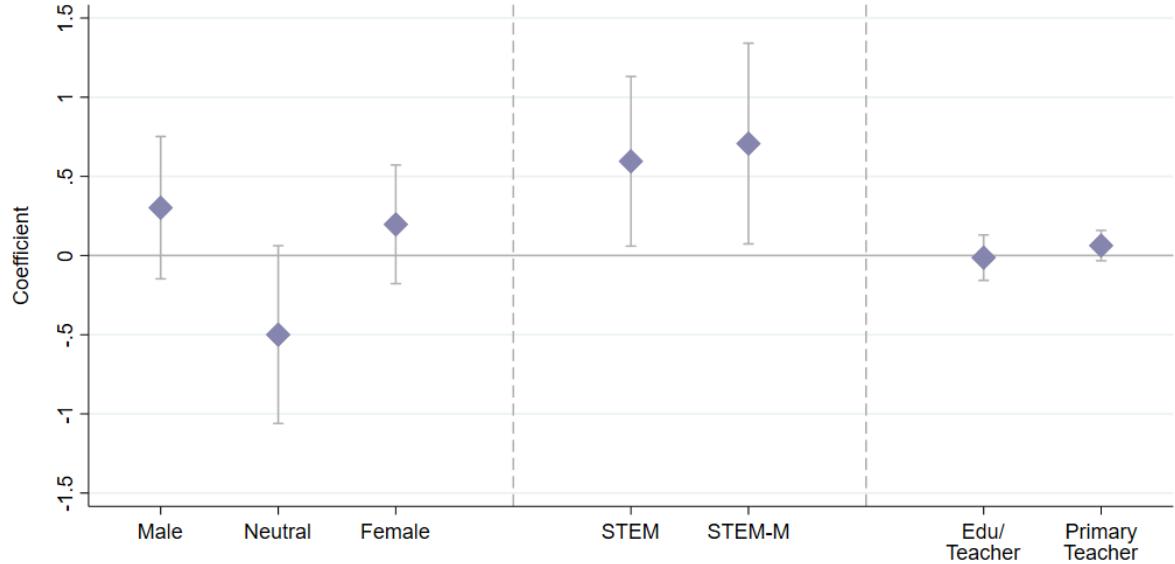

(b) By gender: Applications and enrollment for post-compulsory education

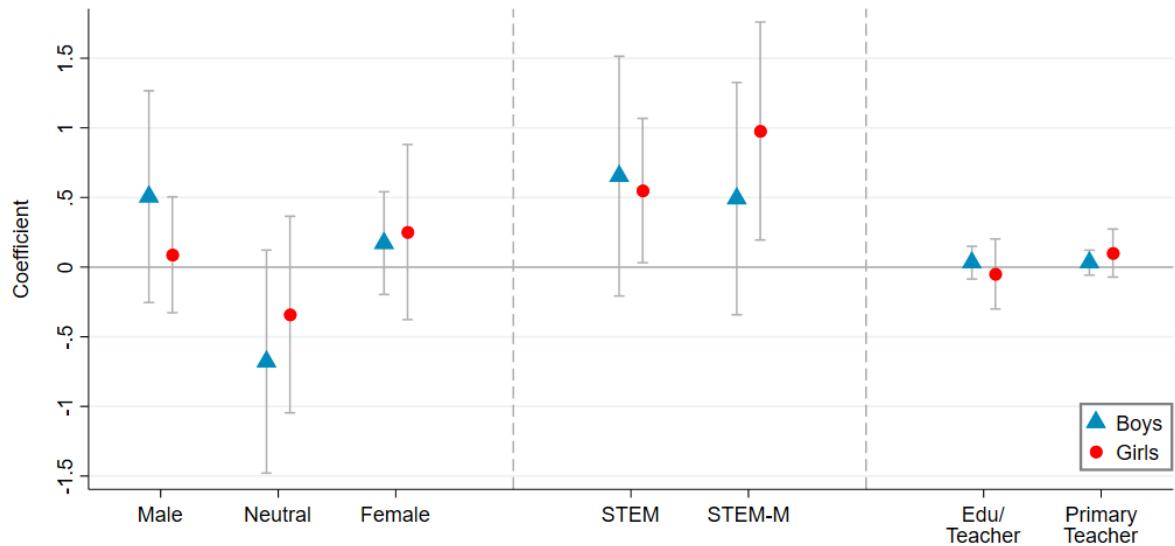

Note: IV estimates of Equation 10. Outcomes from left to right: “Applications” to upper secondary education (mutually exclusive categories): Pupils apply directly in spring of the year in which they turn 16 (Apply directly), they apply up to four years after they have turned 16 (Apply late), or they apply never or later than five years after having turned 16 (Apply never). “Allocation”: Pupils obtain one of their first two preferred choices in the application (Preferred choice), or do not obtain a study slot (No spot). “Enrollment”: Pupils are enrolled in upper secondary education in the fall of the year in which they turn 16 (Enrolled at age 16), and ever enrolled in upper secondary education up to age 25 (Ever enrolled). Individual level controls are measured at age 7 and include gender, language (SE/FI/other), foreign origin, single parent HH, highest level of education in HH. [\(back\)](#)

Figure 11

(a) Education field at age 25

(b) By gender: Education field at age 25

Note: IV estimates of Equation 10, separate regressions by gender. Outcomes from left to right: Field is ‘Male’ dominated ($\geq 40\%$ male), (gender) ‘Neutral’ or ‘Female’ dominated ($\geq 40\%$ female). Field is STEM or STEM + Medicine (STEM-M). Field is Education Science or Teacher. Field is Primary School Teacher. Individual level controls are measured at age 7 and include gender, language (SE/FI/other), foreign origin, single parent HH, highest level of education in HH. Standard errors clustered at the municipality level. [\(back\)](#)

Table 1: Summary statistics of teachers by gender

| Variable | Quota | | | Post Quota | | |
|--|--------|-------|----------------------|------------|-------|----------------------|
| | Female | Male | Difference | Female | Male | Difference |
| <i>A) Background and current place of living</i> | | | | | | |
| Urban residence at birth | 0.586 | 0.562 | -0.023*** (0.007) | 0.612 | 0.590 | -0.022*** (0.007) |
| Rural residence at birth | 0.371 | 0.392 | 0.021** (0.007) | 0.358 | 0.376 | 0.018** (0.006) |
| Born on Russian territory | 0.043 | 0.046 | 0.003 (0.003) | 0.028 | 0.033 | 0.005* (0.002) |
| Finnish mother tongue | 0.922 | 0.947 | 0.025*** (0.004) | 0.916 | 0.940 | 0.024*** (0.004) |
| Lives in region of birth | 0.457 | 0.488 | 0.031*** (0.007) | 0.473 | 0.496 | 0.023*** (0.007) |
| Lives in municipality of birth | 0.229 | 0.268 | 0.039*** (0.006) | 0.249 | 0.277 | 0.028*** (0.006) |
| <i>B) Education path (born after 1952)</i> | | | | | | |
| High school degree | 0.980 | 0.979 | -0.002 (0.003) | 0.983 | 0.980 | -0.003 (0.003) |
| Teaching degree | 0.894 | 0.889 | -0.005 (0.007) | 0.920 | 0.910 | -0.010 (0.006) |
| Age at high school degree | 19.25 | 19.47 | 0.23*** (0.02) | 19.23 | 19.46 | 0.23*** (0.02) |
| Age at teacher degree | 25.54 | 26.50 | 0.96*** (0.09) | 25.48 | 26.48 | 1.00*** (0.09) |
| <i>C) Academic performance (born after 1952)</i> | | | | | | |
| Matriculation exam | 0.984 | 0.981 | -0.003 (0.003) | 0.935 | 0.948 | 0.013** (0.004) |
| National percentile rank, first take | 62.85 | 50.73 | -12.12*** (0.36) | 61.01 | 50.46 | -10.54*** (0.31) |
| National percentile rank, best take | 63.86 | 52.40 | -11.45*** (0.34) | 62.00 | 52.05 | -9.96*** (0.30) |
| Mathematics exam | 0.741 | 0.826 | 0.086*** (0.009) | 0.768 | 0.842 | 0.074*** (0.007) |
| Advanced mathematics exam | 0.277 | 0.380 | 0.103*** (0.010) | 0.263 | 0.380 | 0.117*** (0.008) |

Note: Characteristics of male and female primary school teachers who are active teachers for at least one year in the quota period (1990-93) or in the post quota period (1994-2000) and who are between 24 and 60 years old. ([back](#))

Table 2: First stage at the municipal level

| Dependent variable | First Differences | | | | Fixed Effects | | |
|-----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| | Δ male | | | | share male | | |
| Share 60 | 0.062 (0.038) | 0.062 (0.039) | 0.074* (0.041) | 0.072* (0.039) | | | |
| Share 60 * post | -0.165*** (0.044) | -0.170*** (0.044) | -0.175*** (0.047) | -0.161*** (0.044) | | | |
| Total share 60 | | | | | 0.068 (0.043) | 0.086* (0.045) | 0.078* (0.043) |
| Total share 60 * post | | | | | -0.218*** (0.049) | -0.232*** (0.054) | -0.194*** (0.049) |

| Dep mean | .06 | .03 | .02 | .02 |

Note: Estimates for Equation 9. Outcomes from left to right are: Share of teachers with the birth of a child, share of teachers who are female and have a birth (column 2), and who male and have a birth (column 3), share of teachers who are female and on leave after birth (defined as not being an active teacher in the year subsequent to having given birth). Standard errors clustered at the municipality level. Regressions weighted by population, means unweighted. * p<0.1, ** p<0.05, *** p<0.01 ([back](#))

Table A19: Effect on main outcomes of female teachers having a newborn child

| | Employed/ Student | Un- employed | DI/ Pension | Other out of LF | Apply directly | Apply late | Apply never |
|-----------------------------------|----------------------|-------------------|-------------------|--------------------|-------------------|------------------|------------------|
| Female teachers having a child | -0.003 (0.010) | -0.007 (0.008) | 0.006* (0.003) | 0.003 (0.005) | -0.009 (0.008) | 0.006 (0.008) | 0.003 (0.003) |
| Municipal FE | X | X | X | X | X | X | X |
| Region*Cohort FE | X | X | X | X | X | X | X |
| Ind. controls | X | X | X | X | X | X | X |
| Obs | 811,392 | 811,392 | 811,392 | 811,392 | 825,094 | 825,094 | 825,094 |
| Dep mean | .842 | .086 | .017 | .053 | .911 | .067 | .022 |

Note: Specification equivalent to Equation 11, but estimating the effect of total exposure to female teachers having a newborn child while pupils are in primary school. Standard errors clustered at the municipality level. * p<0.1, ** p<0.05, *** p<0.01 ([back](#))

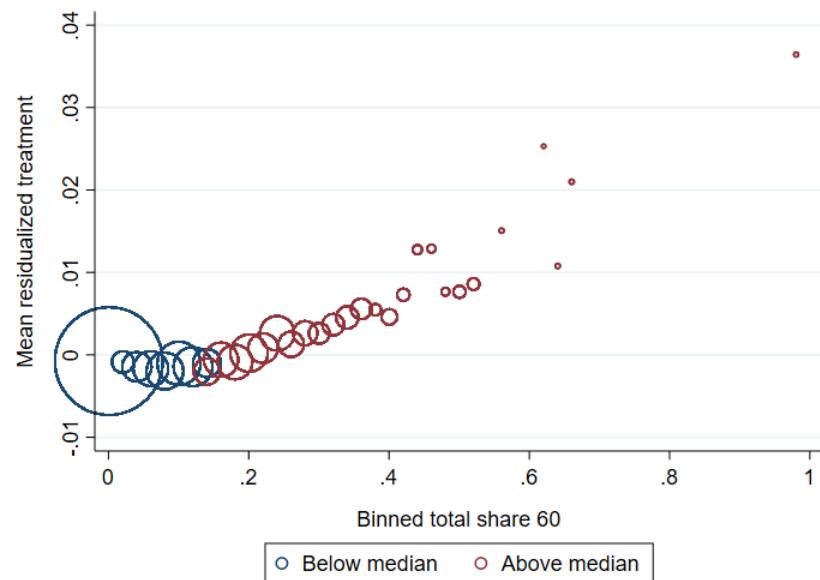

Table A20: Effect on main outcomes of male teachers having a newborn child

| | Employed/ Student | Un- employed | DI/ Pension | Other out of LF | Apply directly | Apply late | Apply never |
|---------------------------------|----------------------|------------------|--------------------|--------------------|-------------------|------------------|------------------|
| Male teachers having a child | -0.021 (0.013) | 0.009 (0.010) | -0.007* (0.004) | 0.018** (0.007) | -0.008 (0.010) | 0.006 (0.009) | 0.002 (0.005) |
| Municipal FE | X | X | X | X | X | X | X |
| Region*Cohort FE | X | X | X | X | X | X | X |
| Ind. controls | X | X | X | X | X | X | X |
| Obs | 811,392 | 811,392 | 811,392 | 811,392 | 825,094 | 825,094 | 825,094 |
| Dep mean | .842 | .086 | .017 | .053 | .911 | .067 | .022 |

Note: Specification equivalent to Equation 11, but estimating the effect of total exposure to male teachers having a newborn child while pupils are in primary school. Standard errors clustered at the municipality level. * p<0.1, ** p<0.05, *** p<0.01 ([back](#))

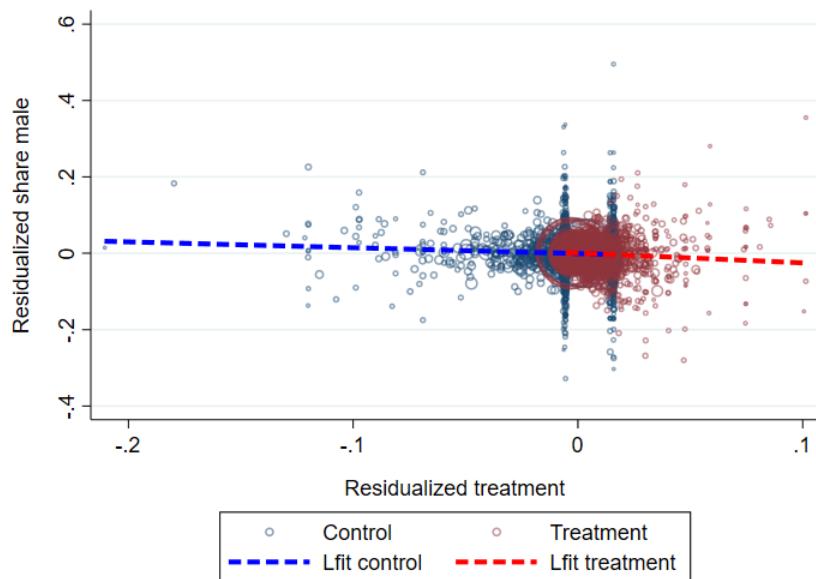

J TWFE robustness

Figure A11: Municipality level: Residuals by treatment intensity

Note: Residuals of Equation 13. Average residual against binned total exposure to retirements in the post period (treatment variable). Weighted by number of municipalities per bin. [\(back\)](#)

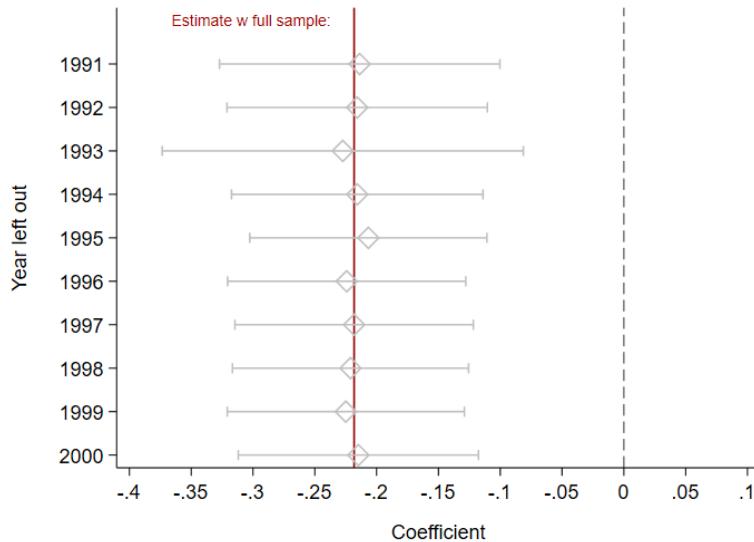

Figure A12: Municipality level: Residual plot

Note: Residual plot of Equation 8 with residualized outcome against residualized treatment. Data and linear fits are population weighted. Each dot is a municipal*year observation. Control observation are those without a retirement in the post-quota period in that municipal*year cell, and Treatment observations are those with a positive retirement value in the post-quota period in that municipal*year cell. [\(back\)](#)

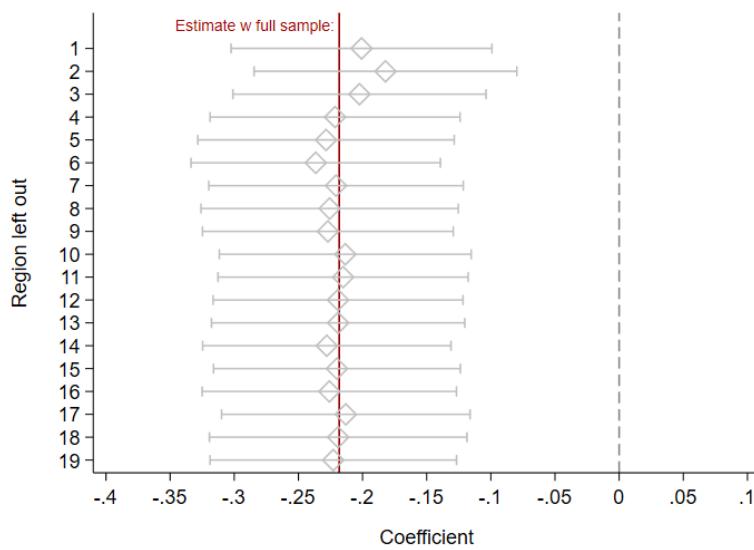

K Leave one out estimation

Figure A13: Municipality level: Leave one out - years

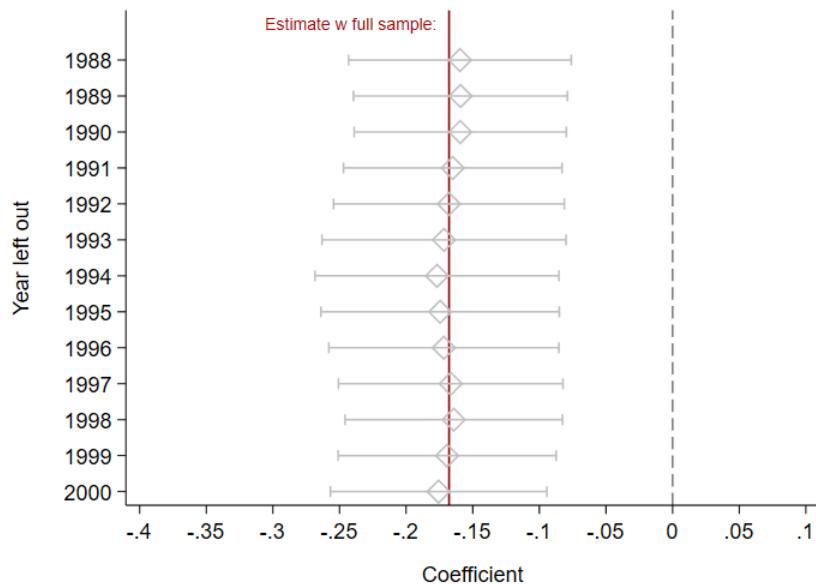

Note: Leave one out estimation of treatment coefficient in Equation 8 with respect to years.
[\(back\)](#)

Figure A14: Municipality level: Leave one out - region

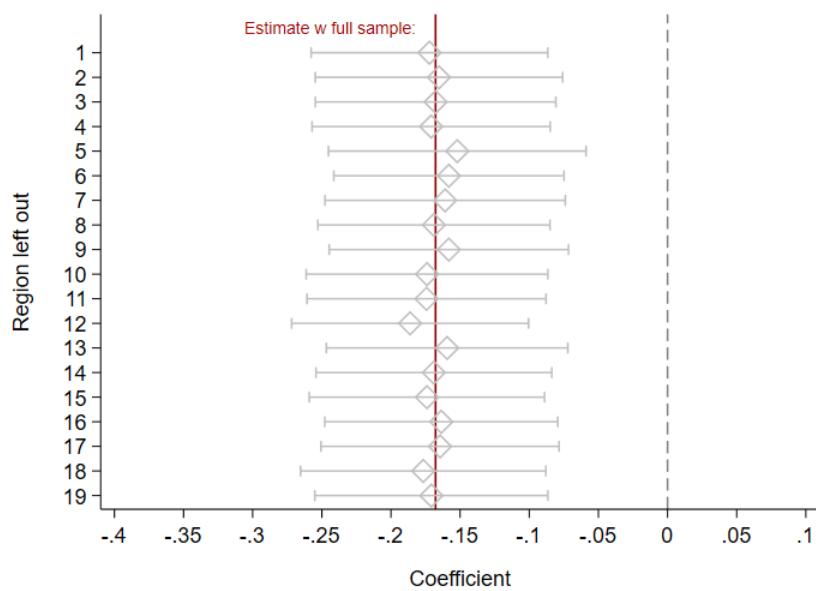

Note: Leave one out estimation of treatment coefficient in Equation 8 with respect to regions.
[\(back\)](#)

Figure A15: Pupil level: Leave one out - cohort

Note: Leave one out estimation of treatment coefficient in Equation 11 with respect to cohorts.

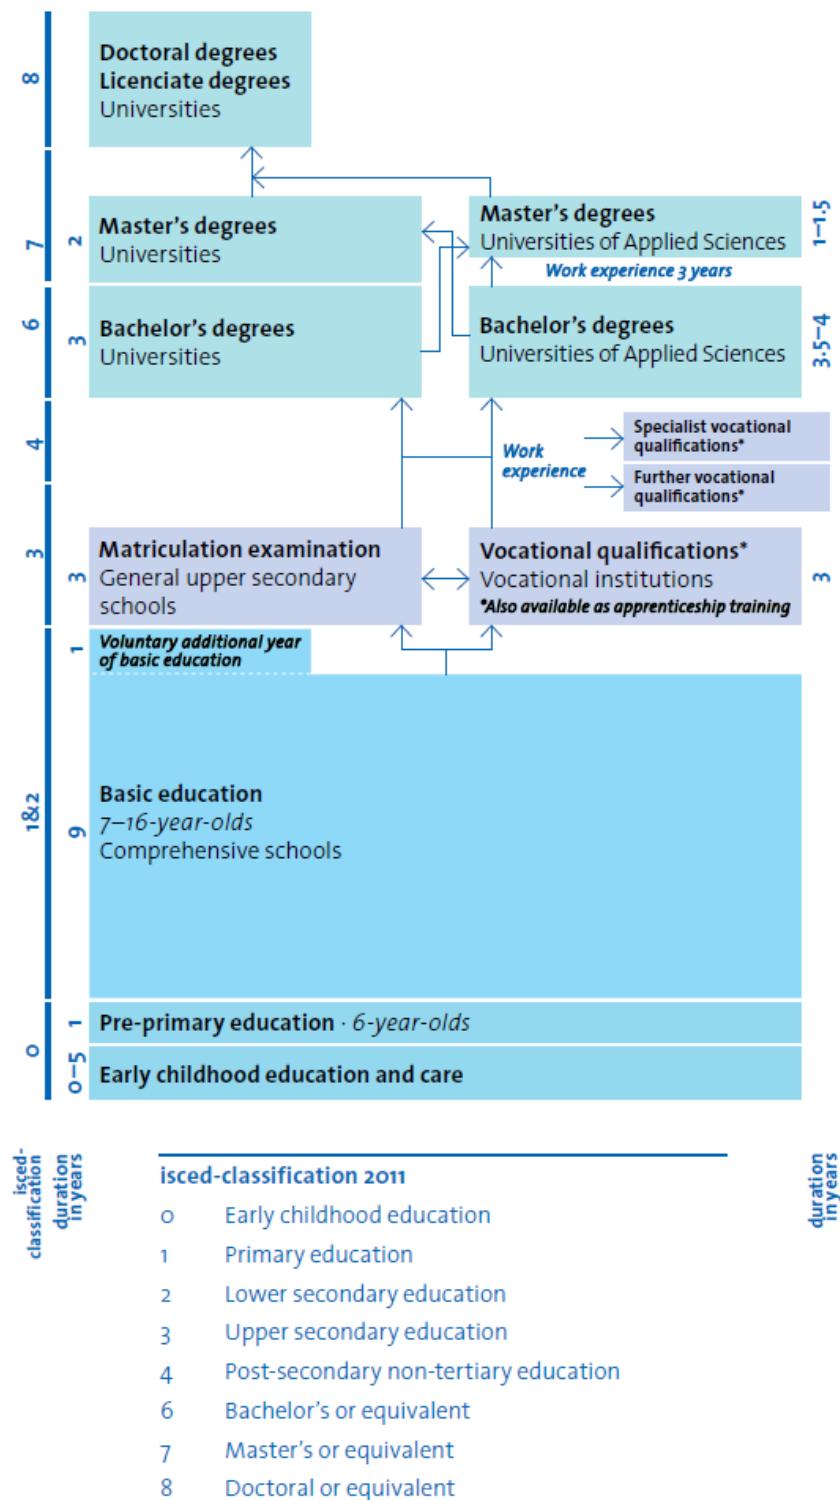

Figure A16: Pupil level: Leave one out - region

Note: Leave one out estimation of treatment coefficient in Equation 11 with respect to regions.
